If there be more in the divisor, we must annex (or suppose annexed) as many cyphers to the dividend as may complete the number in the divisor, and all the figures of the quotient are integers.

If the division leave a remainder, the quotient may be extended to more decimal places; but these are

not regarded in fixing the decimal point.

The reason for fixing the decimal point, as directed, may be inferred from the rule followed in multiplication. The quotient multiplied by the divisor produces the dividend; and therefore the number of decimal places in the dividend is equal to those in the divifor and quotient together.

The first figure of the quotient is always at the same distance from the decimal point, and on the same side as the figure of the dividend, which flands above the unit place of the first product. This also takes place in integers; and the reason is the same in both.

It was formerly observed, that numbers were diminished when multiplied by proper fractions, and increased when divided by the fame. Thus, multiplication by fractions corresponds with division by integers; and division by fractions with multiplication by integers; when we multiply by for .5, we obtain the same anfwer as when we divide by 2, and every integer has a Decimal correspondent decimal, which may be called its reci- Fractions. procal. Multiplication by that decimal supplies the place of division by the integer, and division supplies the place of multiplication.

To find the reciprocal of any number, divide I with

cyphers annexed by that number.

H

Ex. Required the reciprocal of 625.

625)1.000(.0016 625 3750 3750

The product of any number multiplied by .0016 is the same as the quotient divided by 625. Example.

625)9375(15 625			9375 .0016
			-6
3125			56250
3125		•	9375
	•		-
0			15,0000

Because .0016 is gir of unity, any number multiplied by that fraction will be diminished 625 times. For a like reason, the quotient of any number divided by .0016, will be equal to the product of the same multiplied by 625. Example.

SECT. III. APPROXIMATE DECIMALS.

It has been shown that some decimals, though extended to any length, are never complete; and others, which terminate at last, sometimes consist of so many places, that it would be difficult in practice to extend them fully. In these cases, we may extend the decimal to three, four, or more places, according to the nature of the articles, and the degree of accuracy required, and reject the rest of it as inconsiderable. In this manner we may perform any operation with eafe by the common rules, and the answers we obtain are sufficiently exact for any purpose in business. Decimals thus restricted are called approximates.

Shillings, pence, and farthings, may be easily reduced to decimals of three places, by the following rule. Take half the shillings for the first decimal place, and the number of farthings increased by one, if it amount to 24 or upwards; "by two, if it amount to 48 or upwards; and by three, if it amount to 72 or upwards, for the two next places.

The reason of this is, that 20 shillings make a pound, two shillings is the tenth part of a pound; and there-

1 TI H

Decimal fore half the number of shillings makes the first decimal place. If there were 50 farthings in a shilling, or 1000 in a pound, the units of the farthings in the remainder would be thousandth parts, and the tens would be hundredth parts, and fo would give the two next decimal places; but because there are only 48 farthings in a shilling, or 960 in a pound, every farthing is a little more than the thousandth part of a pound; and fince 24 farthings make 25 thousandth parts, allowance is made for that excess by adding I for every 24 farthings, as directed.

> If the number of farthings be 24, 48, or 72, and confequently the fecond and third decimal places 25, 50, and 75, they are exactly right; otherwise they are not quite complete, fince there should be an allowance of 14, not only for 24, 48, and 72 farthings, but for every other fingle farthing. They may be completed by the following rule: Multiply the fecond and third decimal places, or their excels above 25, 50, 75, by 4. If the product amount to 24 or upwards, add 1; if 48, add 2; if 72, add 35. By this operation we obtain two decimal places more; and by continuing the same operation, we may extend the decimal till it terminate in 25, 50, 75, or in a repeater.

> Decimals of sterling money of three places may eafily be reduced to shillings, pence, and farthings, by the following rule: Double the first decimal place, and if the second be 5 or upwards, add I thereto for shillings. Then divide the second and third decimal places, or their excels above 50, by 4, first deducing 1, if it amount to 25, or upwards; the quotient is pence, and the remainder farthings.

> As this tule is the converse of the former one, the reason of the one may be inferred from that of the other. The value obtained by it, unless the decimal terminate in 25, 50, or 75, is a little more than the true value; for there should be a deduction, not only of 1 for 25, but a like deduction of 1 on the remaining figures of these places.

> We proceed to give some examples of the arithmetic of approximates, and subjoin any necessary obser-

SUBTRACTION.
Crut. grs. lb.
3 2 2 = 3.51785
1 1 19 = 1.41964
2 - 9 2.09821

3 24 14.96427

If we value the sum of the approximates, it will fall a little short of the sum of the articles, because the decimals are not complete.

Some add 1 to the last decimal place of the approximate, when the following figure would have been 5, or upwards. Thus the full decimal of 3qrs. 22lb. is .946,428571, and therefore .94643 is nearer to it than .946,42. Approximates, thus regulated, will in general give exacter answers, and sometimes above the true one, fometimes below it.

The mark + fignifies that the approximate is less than the exact decimal, or requires fomething to be added. The mark - fignifies that it is greater, or requires something to be subtracted.

MULTIPLICA	LION.	₩.	1)ecim
8278+	Meth. 2d] 8278	Meth. 3d] 8278	Pracele
2153+	2153	3512	
24834	16556	16556	
41390	827 8	827	
8278	413 90	413	
16556	24 824	2.‡	
	2 - 69 - 10 - 64		

1782 2534 Here the four last places are quite uncertain. The right hand figure of each particular product is obtained by multiplying 8 into the figures of the multiplier; but if the multiplicand had been extended, the carriage from the right hand place would have been taken in; confequently the right hand place of each particular product, and the four places of the total product, which depend on these, are quite uncertain. Since part of the operation therefore is ufcless, we may omicit; and, for this purpose, it will be convenient to begin (as in p. 296. col. 1. fifth variety) at the highest place of the multiplier. We may perecive that all the figures on the right hand of the line in Meth. 2. ferve no purpofe, and may be left out, if we only multiply the figures of the multiplicand, whose products are placed on the right hand of the line. This is readily done by inverting the multiplier in Meth. 3. and beginning each product with the multiplication of that figure which flands above the figure of the multiplier that produces it, and mcluding the carriage from the right hand place.

If both factors be approximates, there are as many uncertain places, at least in the product, as in the longeft factor. If only one be an approximate, there are as many uncertain places as there are figures in that factor, and fometimes a place or two more, which might be affected by the carriage. Hence we may infer, how far it is necessary to extend the approximates, in order to obtain the requifite number of certain places in the product.

DIVISION.

-3724—)798|64327+(2144 or 3724)79864327(2144

74410	7440
53 84 37 24	538 372
16 602 14 896	166 148
1 7063 1 4892	18

Here all the figures on the right hand of the line are uncertain; for the right hand figure of the full product 7448 might be altered by the carriage, if the divifor were extended; and all the remainders and dividuals that follow are thereby rendered uncertain. We may omit these useless figures; for which purpose, we dash a figure on the right hand of the divisor at each step, and neglect it when we multiply by the figure of the quotient next obtained; but we include the carriage. The operation, and the reason of it, will appear clear, by comparing the operation at large, and contracted, in the above example.

Decimals.

CHAP. X. INTERMINATE DECIMALS.

SECT. I. REDUCTION of INTERMINATE DECIMALS.

As the arithmetic of interminate decimals, otherwise called the arithmetic of infinites, is facilitated by comparing them with vulgar fractions, it will be proper to inquire what vulgar fractions produce the several kinds of decimals, terminate or interminate, repeaters or circulates, pure or mixed. And, first, we may observe, that vulgar fractions, which have the same denominator, produce decimals of the same kind. If the decimals corresponding to the numerator I be known, all others are obtained by multiplying these into any given numerator, and always retain the same form, providing the vulgar fraction be in its lowest terms.

Thus, the decimal equal to 4 is .142857, which multiplied by

produces the decimal equal to 3..423571,

Secondly, If there be cyphers annexed to the fignificant figures of the denominator, there will be an equal number of additional cyphers prefixed to the decimal. The reason of this will be evident, if we reduce these vulgar fractions to decimals, or if we consider that each cypher annexed to the denominator diminishes the value of the vulgar fraction ten times, and each cypher prefixed has a like effect on the value of the decimal.

Thus,
$$\frac{1}{10}$$
=.142857, $\frac{7}{15}$ =.28 $\frac{1}{12}$ =.0,45, $\frac{7}{10}$ =.0,142857, $\frac{7}{10}$ =.0028 $\frac{7}{120}$ =.000,45,

We may therefore confine our attention to vulgar fractions, whose numerator is 1, and which have no cyphers annexed to the fignificant figures of the denominator.

Thirdly, Vulgar fractions, whose denominators are 2 or 5, or any of their powers, produce terminate decimals; for if any power of 2 be multiplied by the same power of 5, the product is an equal power of 10, as appears from the following table:

And the reason is easily pointed out; for $2^3 \times 5^3 = 2 \times 2 \times 2 \times 5 \times 5 \times 5$; or, because the factors may be taken in any order, $=2 \times 5 \times 2 \times 5 \times 2 \times 5$; and this, if we multiply the factors by pairs, becomes $10 \times 10 \times 10$, or 10^3 . The like may be shown of any other power. And we may infer, that if any power of 10 be divided by a like power of 2 or 5, the quotient will be an equal power of 5 or 2 respectively, and will come out exact, without a remainder; and, since the vulgar fractions above mentioned are reduced to decimals by some fact division, it follows that the equivalent decimals are terminate.

The number of places in the decimal is pointed out by the exponent of the power; for the dividend must be a like power of 10, or must have an equal number of cyphers annexed to 1, and each cypher of the dividend gives a place of the quotient. Ex. $\frac{r}{31}$ =.03125, a decimal of 5 places, and 32=\frac{1}{2}. Interminat Decimals.

96...

Again, No denominators except 2, 5, or their powers, produce terminate decimals. It is obvious from p. 298. col. 2. par. 4. that, if any denominator which produces a terminate decimal be multiplied thereby, the product will confift of 1, with cyphers annexed; and confequently the lowest places of the factors, multiplied into each other, must amount to 10, 20, or the like, in order to supply a cypher for the lowest place of the product; but none of the digits give a product of this kind, except 5 multiplied by the even numbers; therefore one of the factors must terminate in 5, and the other in an even number. The former is measured by 5, and the latter by 2, as was observed p. 297. col. 2. par. 7. Let them be divided accordingly, and let the quotients be multiplied. This last product will be exactly one-tenth part of the former; and therefore will confit of 1, with cyphers annexed, and the factors which produce it are measured by 5 and 2, as was shown before. This operation may be repeated; and one of the factors may be divided by 5, and the other by 2, till they be exhausted; consequently they are powers of 5 and 2.

Fourthly, Vulgar fractions, whose denominators are 3 or 9, produce pure repeating decimals.

Thus, \$\frac{1}{2} = .111 \\
\$\frac{1}{2} = .222 \\
\$\frac{1}{2} = .222 \\
\$\frac{1}{2} = .333 \\
\$\frac{1}{2} = .444 \\
\$\frac{1}{2} = .888 \\
\$\frac{1}{2} = .444 \\
\$\frac{1}{2} = .

The repeating figure is always the fame as the numerator. Hence we infer, that repeating figures figurify ninth parts; a repeating 3 figurifies \(\frac{1}{2}\); a repeating 6 figurifies \(\frac{2}{2}\); and a repeating 9 figurifies \(\frac{2}{2}\), or 1.

ing 6 fignifies \(\frac{1}{2}\); and a repeating 9 fignifies \(\frac{2}{8}\), or 1.

The value of repeating decimals may also be illustrated by collecting the values of the different places: for example, let the value of 11t be required; the first decimal place fignifies \(\frac{1}{2}\), the next \(\frac{1}{25}\), the next \(\frac{1}{25}\).

The sum of the two first places is \(\frac{1}{25}\), of the three places \(\frac{1}{25}\). The fum of the two first places is \(\frac{1}{25}\), of the three places \(\frac{1}{25}\). The fum of the three places \(\frac{1}{25}\). Thus, when the value of the succeffive figures is reckoned, the amount of them approaches nearer and nearer to \(\frac{1}{2}\), and the difference becomes 10 times less for each figure assumed; and, since the decimal may be extended to any length, the difference will at last become so small, that it need not be regarded. This may give a notion of a decreasing series, whose sum may be exactly ascertained, though the number of terms be unlimited.

Fifthly, Vulgar fractions, whose denominators are a product of 3 or 9 multiplied by 2, 5, or any of their powers, produce mixed repeaters. The reason of this will be evident, if, in forming the decimal, we divide the numerator successively by the component parts of the denominator, as directed p. 297. col. 1. par. ult.

kc.

nterminate &c. The first divisor is 2, 5, or some of their powers, Decimals and consequently gives a finite quotient by p. 316. col. 1. par. 3, &c. The second divisor is 3 or 9; and therefore, when the figures of the dividend are exhausted, and figures annexed to the remainder, the quotient will repeat, by p. 316. col. 2. par. 2.

 E_{x} . $\frac{1}{144}$ 144=16×9.

44)1.000(00694 864	9 or 16)1.00(.0625 96.0069#	
1360	40	
1296	32	
* 640	80	
576	80	
640		

In order to illustrate this subject further, we shall explain the operation of casting out the threes, which refembles that for casting out the nines, formerly laid down, p. 300 col. 2. par. 4. p. 301. col. 2. par. 3. and depends on the same principles, being a method of finding the remainder of a number divided by 3. If the same number be divided by 3 and by 9, the remainders will either agree, or the fecond remainder will exceed the first by 3 or by 6. The reason of this will be obvious, if we suppose a collection of articles afforted into parcels of 3, and afterwards into parcels of 9, by joining three of the former together. If the leffer parcels be all taken up in composing the greater ones, the remainder will be the same at the end of the second affortment as before; but if one of these lesser parcels be lest over, the remainder will be more, and if two of them be left over, the remainder will be 6 more. Therefore, when the nines are cast out from any number, and the result divided by 3, the remainder is the same as when the number is divided by 3: Thus, the refults on casting out the 3's may be derived from those obtained by casting out the g's; and the same correspondence which was pointed out with respect to the latter, for proving the operations of arithmetic, applies also to the former.

To east out the 3's from any number, add the figures, neglecting 3, 6, or 9, and; and when the fum amounts to 3, 6, or 9, reject them, and carry on the computa-tion with the exects only. For example, take 286754: in casting out the 3's we compute thus; 2 and 8 is 10, which is three times 3, and 1, over; 1 and (passing by 6) 7 is 8, which is twice 3 and 2 over; 2 and 5 is 7, which is twice 3 and 1 over; laftly, 1 and 4 is 5, which contains 3 once, and 2 over, fo the refult is 2.

If the 3's be cast out from 2' or 4, the result is 1; from 23 or 8, the refult is 2; from 24 or 16, the refult is 1; and univerfally the odd powers of 2 give a refult of 2, and the even powers give a refult of 1. As every higher power is produced by multiplying the next lower by 2, the result of the product may be found by multiplying the result of the lower power by 2, and casting out the 3's if necessary. fore, if the refult of any power be 1, that of the next higher is 2, and that of the next higher (4 with the 3's cast out or) 1. Thus the results of the powers of 2 are 1 and 2 by turns; also, because the result of 5, when the 3's are cast out, is 2, its powers will have the faine refults as the corresponding powers of 2.

If the denominator be a product of an even power Internal of 2 or 5, multiplied by 3, the repeating figure of the Decimal corresponding decimal is 3; but, if it be the product of an odd power, the repeating figure is 6. For, in forming the decimal, we may divide by the component parts of the denominator, and the first divisor is a power of 2 or 5; therefore the first quotient is a like power of 4 or 2 (p. 316. col. 1. par. 3. &c.) and this power is again divided by 3. If it be an even power, the remainder or result is 1, as was demonstrated above; and if cyphers be annexed to the remainder, and the division continued, it quotes a repeating 3; but if it be an odd power, the remainder is 2, and the quotient continued by annexing cyphers is a repeating 6.

If the denominator be 9, multiplied by 2, or any of its powers, the repeating figure may be found by casting out the 9's from the corresponding power of 5; and if it be multiplied by 5, or any of its powers, by casting out the 9's from the corresponding power of 2. For if the decimal be formed by two divisions, the first quotes the corresponding power; and the second, because the divisor is 9, repeats the resulting figure after

the dividend is exhausted.

If any mixed repeater be multiplied by 9, the product is a terminate decimal, and may be reduced (p. 316. col. 1. par. 3. &c.) to a vulgar fraction, whose denominator is 2, 5, or some of their powers; therefore all mixed repeaters are derived from vulgar fractions, whose denominators are products of 2, 5, or their powers, multiplied by 3 or 9.

Sixthly, All denominators, except 2, 5, 3, 9, the powers of 2 and 5, and the products of these powers, multiplied by 3 or 9, produce circulating decimals. We have already shown, that all terminate decimals are derived from 2, 5, or their powers; all pure repeaters, from 3 or 9; and all mixed repeaters, from the products of the former multiplied by the latter. The number of places in the circle is never greater than the denominator diminished by unity. Thus ; produces .142857 a decimal of 6 places; and 1 produces .0588235294117647, a decimal of 16 places. The reason of this limit may be inferred from the division; for whenever a remainder which has recurred before, returns again, the decimal must circulate, and the greatest number of possible remainder is one less than the divisor: But frequently the circle is much thorter. Thus 1 = .09, a circle of 2 places.

When a vulgar fraction, whose numerator is 1, produces a pure circulate, the product of the circle multiplied by the denominator will confift of as many o's as there are places in the circle. Thus = .142857, which multiplied by 7 produces 999999. The like holds in every decimal of the same kind; for they are formed by dividing 10, or 100, or 1000, or fome like number, by the denominator, and the remainder is 1, when the decimal begins to circulate; for the divition must be then exactly in the same state as at the beginning: Therefore, if the dividend had been less by 1, or had confisted entirely of 9's, the division would have come out without a remainder; and fince the quotient multiplied by the divisor, produces the dividend, as was shown p. 298. col. 2. par. 3. it follows, that the circulating figures, multiplied by the denominator, produce an equal number of 9's.

Every vulgar fraction, which produces a pure circu-

the numerator be 1, the vulgar fraction is reduced to that form by multiplying both terms into the circle of the equivalent decimal; and if the numerator be more than 1, the cultural point the circle of the decimal; and if the numerator be more than 1, the equivalent decimal is found by multiplying that which corresponds to the numerator 1 into any other numerator.

Hence we may infer, that pure circulates are equal in value to vulgar fractions whose numerators consist of the circulating figures, and denominators of as many 9's as there are places in the circle. To place this in another point of view, we shall reduce a vulgar fraction, whose numerator consists entirely of 9's, to a decimal.

'The remainder is now the fame as the dividend, and therefore the quotient must circulate, and, in general, since any number with 3 cyphers annexed, may be divided by 1000, without a remainder, and quotes the significant figures; therefore, when divided by 999, it must quote the fame figures, and leave an equal remainder. 'This also applies to every divisor which consists entirely of 9's. Circles of two places, therefore, figurify ninety ninth parts; circles of 3 places, signify nine hundred and ninety ninth parts; and so on.

The value of circulating decimals may also be illustrated by adding the values of the places. Thus, if two figures circulate, the first circle fignifies hundredth parts, and every following circle fignifies one hundred times less than the preceding; and their values added, as in p. 316. col. 2. par. 3. will approach nearer to ninety ninth parts than any assigned difference, but will never exactly complete it.

All denominators which are powers of 3, except 9, produce pure circulates; and the number of places in the circle is equal to the quotient of the denominator divided by 9.

Thus, \(\frac{1}{27} = .037\), a circle of 3 places, and 27 divided by 9=3
\[
\frac{1}{87} = .012345679\), a circle of 9 places, and 81

divided by 9=9.

These decimals may be formed, by dividing the numerator by the component parts of the denominator. In the first example, the component parts of the numerator are 9 and 3. The division by 9 quotes a pure circulate, and the circulating figure is not 3, 6, or 9, if the sulgar fraction be in its lowest terms. And any other repeating figure divided by 3, quotes a pure circulate of 3 places; for the first dividual must leave a

remainder of 1 or 2. If the first remainder be 1, the Intermin fecond remainder is 2, (because, if 1 be presized to the repeating figure, and the 3's be cast out, the result is 2;) and, for a like reason, the third dividual clears off without a remainder. If the first remainder be 2, the fecond is (twice 2 or 4, with the 3's cast out, or) 1, and the third 0; so the circle is always complete at 3 places, and the division begins anew. The sum of such a circle cannot be a multiple of 3; for since the repeating figure is not 3, nor any of its multiples, the sum of 3 places is not a multiple of 9, and therefore cannot be divided by 9, nor twice by 3, without a remainder.

Again, If the decimal equal to the bedivided by 3, we shall obtain the decimal equal to the Tr. The dividend as we have shown already, is a pure circulate of 3 places, whose sum is not a multiple of 3. Therefore, when divided by 3, the first circle leaves a remainder of 1 or 2, which being presized to the second, and the division continued, the remainder, at the end of the second circle is 2 or 1, and, at the end of the third circle, there is no remainder; all which may be illustrated by cassing out the 3's. The division being completed at 9 places, finishes the circle; and it may be shown, as before, that the sum of these places is not a multiple of 3. The learner will apprehend all this is he reduce these, or the like vulgar fractions, to decimals, by successive divisions.

$$27 = 9 \times 3$$
, and 9)1.0(.1111, and 3).1111(.037, 81 = 27 × 3, and 3)037,037,037(.012345679.

For the fame reason, if any circulating decimal, not a multiple of 3, be divided by 3, the quotient will circulate thrice as many places as the dividend; and if any circulate obtained by such division be multiplied by 3, the circle of the product will be restricted to one third of the places in the multiplicand.

All vulgar fractions, whoic denominators are multiples of 2, 5, or their powers, except those already confidered, produce mixed circulates; for they may be reduced by dividing by the component parts of the denominator. The first divisor is 2, 5, or some of their powers, and therefore gives a finite quotient. The second divisor is none of the numbers enumerated p. 317. col. 2. par. 2. and therefore gives a circulating quotient when the significant figures of the dividend are exhausted, and cyphers annexed to the remainder.

All mixed circulates are derived from valgar frac-

Intermina Decimal

erminate tions of this kind, whose denominators are multiples ceimals. of 2, 5, or their powers; and therefore all other denominators, except 3 and 9, produce pure circulates. The reader will cafily perceive, that when a decimal is formed from a vulgar fraction, whose numerator is 1. when the remainder I occurs in the division, the decimal is a pure circulate; but if any other remainder occurs twice, the decimal is a mixed circulate. We are to show that this last will never happen, unless the divisor be a multiple of 2, 5, or their powers. If two numbers be prime to each other, their product will be prime to both; and if two numbers be proposed, whereof the first does not measure the second, it will not measure any product of the foond, if the multiplier be prime to the first. Thus, because 7 does not meafure 12, it will not measure any product of 12 by a multiplier prime to 7. For instance, it will not meafunc 12 x 3, or 36. Otherwise, the quotient of 12 divided by 7, or 14 multiplied by 3, would be a whole number, and 5 × 3 would be measured by 7, which it cannot be, fince 5 and 3 are both prime to 7.

> Now, if we inspect the foregoing operation, we shall perceive that the product of 136, the remainder where the decimal begins to circulate, multiplied by 999, is measure by the denominator 216. But 999 is not meafur i by the denominator, otherwise the decimal would have been a pure circulate; therefore 126 and 136 are not prime to each other, but have a common measure, and that measure must apply to 864, a multiple of 126, and to 1000, the fum of 136 and 864; see p. 309, col. 2. par. utt. &c. But it was proven, p. 316. col. 1. par. 1. that no numbers, except the powers of g and 2, measure a number consisting of I with cyphera annexed; confequently the denominator must be measured by a power of 2 or 5. The reader will perceive, that the exponent of the power must be the same as the number of cyphers annexed to 1, or as the number of figures in the finite part of the decimal.

> We shall now recapitulate the substance of what has been faid with respect to the formation of decimals. 2, 5, and their powers, produce finite decimals, by p. 316. col. 1. par 3. &c. and the number of places is meafured by the exponent of the power. 3 and 9 produce pure repeaters (p. 316. col. 2. par. 2.) The products of 2, 5, and their powers, by 3 or 9, produce mixed repeaters by p. 316. col. 2. par. ult.; their products by other multipliers, produce mixed circulates by p. 316. col. 2. par. ult.; and all numbers of which 2 and 5 are not aliquot parts, except 3 and 9, produce pure circulates. To find the form of a decimal corresponding to any denominater, divide by 2, 5, and 10, as often as can be done without a remainder; the number of divitions shows how many finite places there are in the decimal, by p. 318. col. 2. par. 3. If the dividend be not exhaulted by these divisions, divide a competent nember of 9's by the last quotient, till the division he completed without a remainder: the number of 9's required show how many places there are in the circle; and the reason may be inferred from p. 317. col. 2 par. 5.

> We shall conclude this subject by marking down the decimals produced by vulgar fractions, whose numerator is 1, and denominators 30; and under that the reader may observe their connexion with the denominators,

RULFS for reducing interminate decimals to vulgar fractions.

I. "If the decimal be a pure repeater, place the
repeating figure for the numerator, and 9 for the
denominator."

II. " If the decimal be a pure circulate, place the "circulating figures for the numerator, and as many 9's " as there are places in the circle for the denominator."

'II. "If there be cyphers prefixed to the repeating "or circulating figures, annex a like number to the "9's in the denominator."

IV. " If the decimal be mixed, fubtract the finite "part from the whole decimal. The remainder is the "numerator; and the denominator confills of as many og's as there are places in the circle, together with "as many cyphers as there are finite places before the "circle."

Thus, 235,62,=23555 From the whole decimal 23562 We fubtract the finite part 235

and the remainder 23327 is the numerate.

The reason may be illustrated by dividing the decimal into two parts, whereof one is finite, and the other a pure repeater or circulate, with cyphers prefixed. The sum of the vulgar fractions corresponding to these will be the value of the decimal fought.

.235,62, may divided into .235 = 235 by rule I.
and .000,62= 5,22 by rules II. III.
In order to add these vulgar fractions, we reduce them to a common denominator; and, for that purpose, we multiply both t rms of the former by 99,

which gives #3565; then we add the numerators.

235 or by method explained p. 295. col. 1. par. 3.

99		Sum of nu	merators.
2115 2115	23500 235	23265 UI 62	23562 235
		-	
22265	20265	22227	20227

The value of circulating decimals is not altered, though one or more places be feparated from the circle, and confidered as a finite part, providing the circle be completed. For example, .27 may be written .2,72, which is reduced by the last of the foregoing rules to $\frac{1}{2}\sqrt{6}$, or $\frac{2}{2}\sqrt{6}$, which is also the value of .27. And if two or more circles be joined, the value of the decimal is still the same. Thus, 2727, = $\frac{1}{2}\sqrt{6}$ which is reduced by dividing the terms by 101 to $\frac{3}{2}\sqrt{6}$.

All circulating decimals may be reduced to a similar form, having a like number both of sinte and circulating places. For this purpose, we extend the finite part of each as far as the longest, and then extend all the circles to so many places as may be a multiple of the number of places in each.

Ex. .34,725, extended, .34,725725725725, 1,4562, 14,562456245624.

Here the finite part of both is extended to two places, and the circle to 12 places, which is the least multiple for circles of 3 and 4 places.

SECT. II. Addition and Subtraction of Interminate Decimals.

To add repeating Decimals. "Extend the repeating "figures one place beyond the longest finite ones, and "when you add the right hand column, carry to the "next by 9."

264046

To fubtrast repeating decimals. "Extend them as "directed for addition, and borrow at the right hand "place, if necessary, by 9."

.08724 .11172

The reason of these rules will be obvious, if we recollect that repeating figures signify minth parts. If the right hand signic of the sum or remainder be 0, the decimal obtained is finite; otherwise it is a repeater.

To add circulating decimals. "Extend them till they "become fimilar (p. 319. col. 1. par. ult. &c.); and "when you add the right hand column, include the fi"gure which would have been carried if the circle had "been extended further."

	-		

1.652,284, 1.503,026390, Note 1. Repeaters mixed with circulates are extended and added as circulates.

Note 2. Sometimes it is necessary to inspect two or more columns for ascertaining the carriage; because the carriage from a lower column will sometimes raise the sum of the higher, so as to alter the carriage from it to a new circle. This occurs in Ex. 2.

Note 3. The fum of the circles must be considered as a similar circle. If it consist entirely of cyphers, the amount is terminate. If all the figures be the same, the amount is a repeater. If they can be divided into parts exactly alike, the amount is a circle of fewer places; but, for the most part, the circle of the sum is similar to the extended circles.

SECT. III. MULTIPLICATION of INTERMINATE DI-

Case I. "When the multiplier is finite, and the "multiplicand repeats, carry by 9 when you multiply "the repeating figure: The right hand figure of each "line of the product is a repeater; and they must be extended and added accordingly."

.04952461

If the sum of the right hand column be an even number of 9's, the product is finite; otherwise, it is a repeater.

CASE II. "When the multiplier is finite, and the "multiplicand circulates, add to each product of the right hand figure the carriage which would have been brought to it if the circle had been extended. Each line of the product is a circle fimilar to the "multiplicand, and therefore they must be extended and added accordingly."

The product is commonly a circulate similar to the multiplicand; sometimes it circulates fewer places, repeats, or becomes sinute; it never circulates more places.

.08804,19,

Case III. "When the multiplier repeats or cir"culates, find the product as in finite multipliers, and
"place under it the products which would have arisen
"from the repeating or circulating figures, if extend"ed."

3 T

Chap. X.

METIC.

Decimals.

3d.] .714285, × 54, 2850142 35714285 38,571428 571428 | 571428, 285714 285714, 385714 3857 142857 142857, 571428 571428, 285714, 385714 3857 142875,

It is evident, that if a repeating multiplier be extended to any length, the product arising from each figure will be the same as the first, and each will stand one place to the right hand of the former. In like manner, if a circulating multiplier be extended, the product arising from each circle will be alike, and will

38.961038,961038,961038,

product arising from each circle will be alike, and will stand as many places to the right hand of the former as there are figures in the circle. In the foregoing examples, there are as many of these products repeated as is necessary for finding the total product. If we place down more, or extend them further, it

will only give a continuation of the repeaters or circulates.

This is obvious in Ex. 1st and 2d. As the learner may not apprehend it so readily in Ex. 3d, when the multiplicand is a circulate, and confequently each line of the product is also a circulate, we have divided it into columns, whose sums exhibit the successive circles. The fum of the first column is 38,961037, and there is a carriage of 1 from the right hand column, which completes 38,961038. This one is furplied from the three first lines of the second column, the sum of which is 99999, and being increased by I, in consequence of the carriage from the third column, amounts to 1,000000, and therefore carries I to the first column, and does not affect the fum of the remaining lines, which are the same as those of the first column. The third column contains two fets of these lines, which amount to 999999, belides the line which compose the circle. Each of these sets would be completed into 1,000000 by the carriage from the 4th column, if extended, and each would carry I to the fecond column. One of these would complete the sum of the three first lines, and the other would complete the fum of the circle. In like manner, if the circles be extended ever so far, the increasing carriages will exactly answer for the increasing deficiencies, and the sum will be always a continuation of the circle; but the product could not circulate, unless the sum of the lines marked off in the second column had consisted entirely of 9's; or had been some multiple of a number of 9's; and the circles must be extended till this take place, in order to find

the complete product. Vol. II. Part I. The multiplication of intermediate decimals may be latermine often facilitated, by reducing the multiplier to a vulgar fraction, and proceeding as directed p. 311. col. 1. par. 6.

Thus,

4th.]
$$.3824 \times 1.3 = \frac{7}{5}$$
 5th.] $.384 \times .23 = \frac{11}{55}$

$$-\frac{7}{9)2.6768}$$

$$.9742$$

$$-\frac{768}{90)8.832}$$

$$.09813$$

Therefore, in order to multiply by 3, we take onethird part of the multiplier; and, to multiply by 6, we take two-thirds of the same. Thus,

.6th.]
$$.784 = .3 \times \frac{1}{3}$$
 7th,] $.8761 \times .6 = \frac{2}{3}$
3).784 $\frac{2}{3}$ 3)1.7522 $.584 \circ 6$

As the denominator of the vulgar fractions always confifts of 9's, or of 9's with cyphers annexed, we may use the contraction explained p. 298. col. 1. par. ult. &c.; and this will lead us exactly to the same operation which was explained p. 320. col. 2. par. ult. &c. on the principles of decimal arithmetic.

8th.]
$$.735 \times .3,26,=\frac{11}{9}\frac{1}{9}$$
 9th.] $.278 \times 365,=\frac{1}{9}\frac{6}{9}$

$$\begin{array}{r}

\hline
.239803,
\end{array}$$

When the multiplier is a mixed repeater or circulate, we may proceed as in Ex. 5th and 8th; or we may divide the multiplier into two parts, of which the first is finite, and the second a pure repeater or circulate, with cyphers prefixed, and multiply separately by these, and add the products.

In the following examples, the multiplicand is a repeater; and therefore the multiplication by the numerator of the vulgar fraction is performed as directed p. 320. col. 2. par. 2.

Sf 10th.]

In the following examples the multiplicand is a circulate, and therefore the multiplication by the numerator is performed as directed p. 320. col. 2. par. 4.

* 036

In Ex. 13th, we have omitted the products of the Intermignation, and only marked down the remainders. These Decimals are found, by adding the left hand figure of the dividual to the remaining figures of the fame. Thus, 363 is the first dividual, and 3 the left hand figure, added to 63, the remaining figures gives 66 for the first remainder; and the second dividual, 666, is completed by annexing the circulating figure 6. The reason of which may be explained as follows. The highest place of each dividual shows, in this example, how many hundreds it contains; and as it must contain an equal number of ninety-nines, and also an equal number of units, it follows, that these units, added to the lower places, must show how far the dividual exceeds that number of ninety-nines. The figure of the quotient is generally the same as the first place of the dividual, sometimes one more. This happens in the last step of the foregoing example, and is discovered when the remainder found, as here directed, would amount to 99, or upwards; and the excess above 99 only, must in that case be taken to complete the next dividual.

14th.].01, ×.01,===

99).01,(000102030405060708091011121314151617181920 (2182232425262728292031323234353637383940 (4142434445464748495031523354535657385960 (6162636465666768697071727374757677787980 (81828384858687888990919293949596979899

The number of places in the circle of the product is fometimes very great, though there be few places in the factors: but it never exceeds the product of the denominator of the multiplier, multiplied by the number of places in the circle of the multiplicand. Therefore, if the multiplier be 3 or 6, the product may circulate three times as many places as the multiplicand s if the multiplier be any other repeater, nine times as many; if the multiplier be a circulate of two places, ninety-nine times as many; thus, in the last example, .01, a circulate of two places, multiplied by .10, a circulate of two places, produces a circulate of twice 99, or 198 places. And the reason of this limit may be inferred from the nature of the operation; for the greatest possible number of remainders, including o, is equal to the divisor 99; and each remainder may afford two dividuals, if both the circulating figures, 3 and 6, occur to be annexed to it. If the multiplier circulate three places, the circle of the product, for a like reafon, many extend nine hundred and ninety-nine times as far as that of the multiplicand. But the number of places is often much lefs.

The multiplication of interminate decimals may be proven, by altering the order of the factors, (p. 295, col. 2. par. 2.) or by reducing them both to vulgar fractions in their lowest terms, multiplying these as directed p. 310. col. 2. par. 3. and reducing the product to a decimal.

SECT. IV. DIVISION of INTERMINATE DECIMALS.

Case I. "When the dividend only is interminate, "proceed as in common arithmetic; but, when the figures of the dividend are exhausted, annex the re"peating figure, or the circulating figures in their order, instead of cyphers, to the remainder."

ARITHMETIC

Interminate Ex. 1st.] Divide.5376 by 7 2d.] Divide .843 by 5. Decimals .7).5376(.76,095238, .5)843(.1686

* 066	

In these accounts the quotient is never finite. It may repeat if the dividend repeats; or, if the dividend circulate, it may circulate, a qual number of places, often more, and never few. The greatest possible extent of the circle is found by municipying the divisor into the number of places in the circle of the dividend. Thus, a circulate of 3 places, divided by 3, quotes a circulate of 3 times 3, or 9 places.

CASE II. "When the divitor is interminate, the mul-"tiplications and subtractions must be performed according to the directions given for repeating and circulating decimals."

Ex. 1st.] Divide .37845 by g. 8).37845 (.68121

2d.] Divide .245892 by 2,18, .2,18,).245892(1.127005 218181,81,

27710,18,

21818,18,
5892,00, 4363,63,
1528,36, 1527,27,
1090,9

The foregoing method is the only one which pro-Estraction perly depends on the principles of decimal arithmetic; of Roote but it is generally shorter to proceed by the following rule.

"Reduce the divifor to a vulgar fraction, multiply the dividend by the denominator, and divide the product by the numerator."

Ex. ift.] Divide .37845 by
$$g = \frac{5}{5}$$

5)3.40605(.68121

2d.] Divide .37848 by $g = \frac{7}{5}$

3
2)1.13536(.567683

Note 1. Division by 3 triples the dividend, and division by 6 increases the dividend one-half.

Note 2. When the divisor circulates, the denominator of the vulgar fraction confists of 9's, and the multiplication is sooner performed by the contraction explained p. 295. col. 1. par. 1. It may be wrought in the same way, when the divisor repeats, and the denominator, of consequence, is 9.

Note 3. If a repeating dividend be divided by a repeating or circulating divifor; or, if a circulating dividend be divided by a fimilar circulating dividend; or, if the number of places in the circle of the divifor be a multiple of the number in the dividend; then the product of the dividend multiplied by the denominator of the divifor will be terminate, fince like figures are fubtracted from like in the contracted multiplication, and confequently no remainder left. The form of the quotient depends on the divifor, as explained at large, p. 316. col. 1. par. 1.—p. 318. col. 2. par. 3.

Note 4. In other cases, the original and multiplied dividend are similar, and the form of the quotient is the same as in the case of a smite divisor. See p. 322. col. 2. par. ult. &c.

Note 5. If the terms be fimilar, or extended till they become so, the quotient is the same as if they were finite, and the operation may be conducted accordingly; for the quotient of vulgar fractions that have the same denominator is equal to the quotient of their numerators.

CHAP. XI. OF THE EXTRACTION OF ROOTS.

THE origin of powers by involution has already been explained under the article ALGERA. There now remains therefore only to give the most expeditious methods of extracting the square and cube roots; the reasons of which will readily appear from what is said under that article. As for all powers above the cube, unless such as are multiples of either the square and cube, the extraction of their roots admits of no deviation from the algebraic canon which must be always constructed on purpose for them.

If the root of any power not exceeding the feventh power be a fingle digit, it may be obtained by inspection, from the following TABLE of powers. 4 2

ıft,

t

3d.] Required the square root of .3916.

If the square root of a vulgar fraction be required, find the root of the given numerator for a new numerator, and find the root of the given denominator for a new denominator. Thus the square root of 4 is 3, and the root of $\frac{1}{2}$ is $\frac{1}{2}$; and thus the root of $\frac{1}{2}$ $(=6\frac{1}{2})$ is $\frac{1}{2}=2\frac{1}{2}$.

But if the root of either the numerator or denominator cannot be extracted without a remainder, reduce the vulgar fraction to a decimal, and then extract the root, as in Ex. 3d. above.

SECT. II. EXTRACTION OF THE CUBE ROOT.

Rule. I. "Divide the given number into periods " of three figures, beginning at the right hand in in-" tegers, and pointing toward the left. But is deci-" mals, begin at the place of thousands, and point to-" ward the right. The number of periods shows the " number of figures in the root."

II. "Find by the table of powers, or by trial, the " nearest lesser root of the lest hand period; place the "figure fo found in the quot; fubtract its cube from "the faid period; and to the remainder bring down "the next period for a dividual or refolvend."

The divisor confists of three parts, which may be found as follows.

SECT. I. EXTRACTION OF THE SQUARE ROOT.

Rulle I. "Divide the given number into periods " of two figures, beginning at the right hand in inte-" gers, and pointing toward the left. But in deci-" mals, begin at the place of hundreds, and point to-" ward the right. Every period will give one figure " in the root."

11. " Find by the table of powers, or by trial, the " nearest lesser root of the left hand period, place the " figure fo found in the quot, subtract its square from " the faid period, and to the remainder bring down "the next period for a dividual or refolvend."

III. "Double the quot for the first part of the " divifor; inquire how often this first part is contained "in the whole refolvend, excluding the units place; " and place the figure denoting the answer both in "the quot and on the right of the first part; and you " have the divifor complete."

IV. " Multiply the divisor thus completed by the " figure put in the quot, subtract the product from " the resolvend, and to the remainder bring down the " following period for a new refolvend, and then pro-" ceed as hefore."

Note 1st. If the first part of the divisor, with unity funnofed to be annexed to it, happen to be greater than the refolvend, in this case place o in the quot, and also on the right of the partial divisor; to the resolvend bring down another period; and proceed to divide as

Note 2. If the product of the quotient figure into the divisor happen to be greater than the resolvend, you must go back, and give a lesser figure to the quot.

Note 3. If, after every period of the given number is brought down, there happen at last to be a remainder, you may continue the operation, by annexing periods or pairs of cyphers, till there be no remainder, or till the decimal part of the quot repeat or circulate, or till you think proper to limit it.

Ex. 1st. Required the square root of 133225.

97384 rem.

If the cube root of a vulgar fraction be required, find the cube root of the given numerator for a new numerator, and the cube root of the given denominator for a new denominator. Thus, the cube root of $\frac{8}{27}$ is $\frac{2}{3}$, and the cube root of $\frac{27}{64}$ is $\frac{3}{4}$; and thus the

cube root of $\frac{1+3}{5}$ (=15 $\frac{4}{5}$) is $\frac{1}{1}$ = 2 $\frac{1}{5}$.

But if the root of either the numerator or denomination nator cannot be extracted without a remainder, reduce the vulgar fraction to a decimal, and then extract the root.

ARI

ARIUS, a divine of the fourth century, the head and founder of the ARIANS, a fect which denied the eternal divinity and fubstantiality of the Word. He was born in Libya, near Egypt. Eusebius, bishop of Nicomedia, a great favourite of Constantia, fifter of the emperor Constantine, and wife of Licinius, became a zealous promoter of Arianism. He took Arius under his protection, and introduced him to Constantia; so that the fect increased, and several bishops embraced it openly. There arose, however, such disputes in the cities, that the emperor, in order to remedy these disorders, was obliged to assemble the council of Nice, where, in the year 325, the doctrine of Arius was condemned. Arius was banished by the emperor, all his books were ordered to be burnt, and capital punishment was denounced against whoever dared to keep them. After five years banishment, he was recalled to

ARI

Constantinople, where he presented the emperor with a confession of his faith, drawn up so artfully, that it fully fatistied him. Notwithstanding which, Athanafius, now advanced to the see of Alexandria, refused to admit him and his followers to communion. This fo enraged them, that, by their interest at court, they procured that prelate to be deposed and banished. But the church of Alexandria still refusing to admit Arius into their communion, the emperor fent for him to Constantinople; where, upon delivering in a fresh confession of his faith in terms less offensive, the emperor commanded Alexander, the bishop of that church, to receive him the next day into his communion: but that very evening Arius died. The manner of his death was very extraordinary: as his friends were conducting him in triumph to the great church of Constantinople, Arius, pressed by a natural necessity, stepped aside to case

himself; but expired on the spot, his bowels gushing

But the herefy did not die with the herefiarch: his party continued fill in great credit at court. Athanafius, indeed, was foon recalled from banishment, and as foon removed again; the Arians being countenanced by the government, and making and deposing bishops as it best served their purposes. In short, this sect continued with great suffer above 300 years: it was the reigning religion of Spain for above two centuries; it was on the throne both in the east and west; it prevailed in Italy, France, Pannonia, and Africa; and was not extirpated till about the end of the 8th century.

This herefy was again fet on foot in the west by Servetus, who, in 1531, wrote, a little treatise against the mystery of the Trinity. After his death Arianism got footing in Geneva; from whence it removed into Poland; but at length degenerated, in a great measure, into Socinianism. Erasmus seems to have aimed at reviving Arianism, in his Commentaries on the New Testament; and the learned Grotius seems to lean a

little that way.

ig. I.

With regard to the state of Arianism in England, it may be sufficient to observe, that from the numerous publications of that cast which are daily making their appearance, it seems to be rather a growing, than explate Lill.

Plate Lill.

ARK, or Noah's ARK, a floating vessel built by Noah, for the preservation of his family, and the several species of animals during the deluge.

The ark has afforded feveral points of curious inquiry among the critics and naturalists, relating to its

form, capacity, materials, &c.

The wood whereof the ark was built is called in the Hebrew Gopher wood, and in the Septuagint fquare timbers. Some translate the original cedar, others pine, others box, &c. Pelletier prefers cedar on account of its incorruptibility, and the great plenty of it in Asia; whence Herodotus and Theophrastus relate, that the kings of Egypt and Syria built whole sleets thereof, instead of deal.

The learned Mr Fuller, in his Miscellanies, has observed, that the wood whereof the ark was built was
nothing but that which the Greeks call **evaces**, or
the express tree; for, taking away the termination, **epar and gopher differ very little in sound. This observation the great Bochart has consirmed, and shown
very plainly that no country abounds so much with
this wood as that part of Assyria which lies about Babylon.

In what place Noah built and finished his ark is no less made a matter of disputation. But the most probable opinion is, that it was built in Chaldea, in the territories of Babylon, where there was so great a quantity of cypress in the groves and gardens in Alexander's time, that that prince built a whole sleet out of it for want of timber. And this conjecture is consirmed by the Chaldean tradition, which makes Kisuthrus (another name for Noah) set sail from that country.

The dimensions of the ark, as given by Moses, are 300 cubits in length, 50 in breadth, and 30 in height; which some have thought too scanty, considering the number of things it was the contain; and hence an argument has been drawn against the authority of the relation. To solve this difficulty many of the ancient

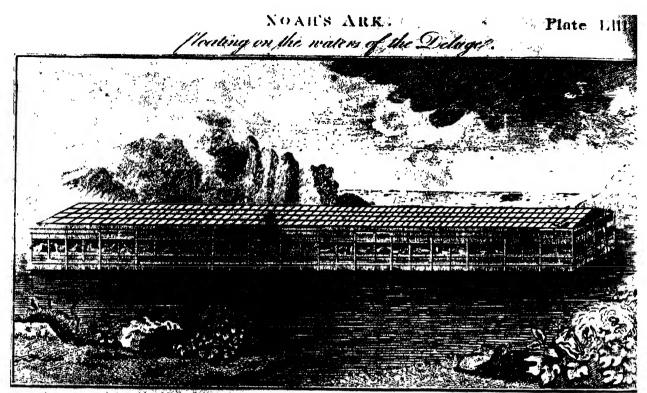

fathers and the modern critics, have been put to very miferable shifts: But Buteo and Kircher have proved geometrically, that taking the common cubit of a foot and a-half, the ark was abundantly sufficient for all the animals supposed to be lodged in it. Snellius computes the ark to have been above half an acre in area. Father Lamy shows, that it was 110 feet longer than the church of St Mary at Paris, and 64 feet narrower and if so, it must have been longer than St Paul's church in London, from west to east, and broader than that church is high in the inside, and 54 feet of our measure in height; and Dr Arbuthnot computes it to have been 81062 tons.

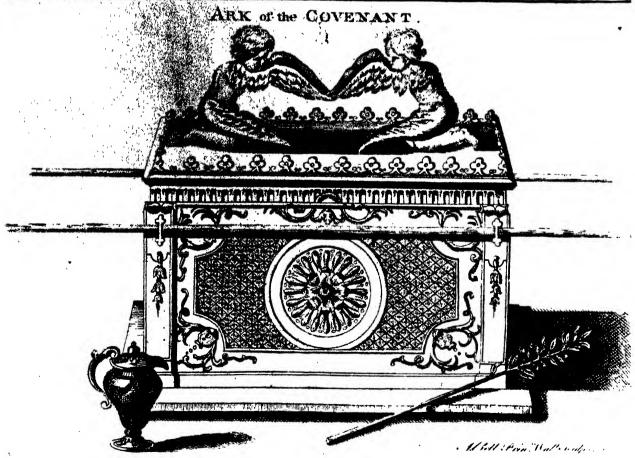

The things contained in it were, besides eight perfons of Noah's family, one pair of every species of unclean animals, and seven pair of every species of clean animals, with provisions for them all during the whole year. The former appears, at first view, almost insinite; but if we come to a calculation, the number of species of animals will be found much less than is generally imagined; out of which, in this case, are excepted such animals as can live in the water; and Bishop Wilkins shows that only 72 of the quadruped kind

needed a place in the ark.

By the description Moses gives of the ark, it appears to have been divided into three stories, each ten cubits or 15 feet high; and it is agreed on, as most probable, that the lowest story was for the beasts, the middle for the food, and the upper for the birds, with Noah and his family; each flory being subdivided into different apartments, stalls, &c. though Josephus, Philo, and other commentators, add a kind of fourth flory under all the reft; being, as it were, the hold of the vessel, to contain the bellast and receive the filth and feces of fo many animals : but F. Calmet thinks, that what is here reckoned a story, was no more than what is called the keel of thins, and ferved only for a confervatory of fresh water. Drexelius makes 300 apartments; F. Fournier, 333; the anonymous author of the questions on Genesis, 400; Buteo, Temporarius, Arias Montanus, Hoftus, Wilkins, Lamy, and others, suppose as many partitions as there were different forts of animals. Pelletier makes only 72, viz. 36 for the birds, and as many for the beafts. His reaion is, that if we suppose a greater number, as 333 or 400, each of the eight perions in the ark must have had 37, 41, or 50 stalls to attend and cleanse daily, which he thinks impossible to have been done. But it is observed, that there is not much in this : to diminish the number of stalls without the diminution of animals is in vain; it being perhaps more difficult to take care of 300 animals in 72 stalls than in 300. As to the number of animals contained in the ark, Buteo computes that it could not be equal to 500 horses; he even reduces the whole to the dimensions of 56 pair of oxen. F. Lamy enlarges it to 64 pair of oxen, or 128 oxen; fo that, supposing one ox equal to two horfes, if the ark had room for 256 horses, there must have been room for all the animals. But the same author demonstrates, that one floor of it would suffice for 500 horfes, allowing nine fquare feet to a horfe.

As to the food in the second story, it is observed by Buteo from Columella, that 30 or 40 pounds of hay ordinarily suffices for an ox a-day; and that a solid cubit of hay, as usually pressed down in our hay ricks,

Ark Arles

weighs about 40 pounds; so that a square cubit of hay is more than enough for one ox in one day. Now, it appears, that the second story contained 150,000 folid cubits; which divided between 206 oxen, will afford each more hay, by two-thirds, than he can est in a year. Bishop Wilkins computes all the carnivorous animals equivalent, as to the bulk of their bodies, and their foods to 27 wolves, and all the rest to 280 beeves. For the former he allows 1825 sheep; and for the latter, 100,500 cubits of hay: all which will be easily contained in the two first stories, and a deal of room to spare. As to the third story, nobody doubts of its being sufficient for the fowls; with Noah, his sons, and daughters. Upon the whole, the learned bishop remarks, that of the two, it appears much more difficult to affign a number and bulk of necessary things to answer the capacity of the ark, than to find sufficient room for the feveral species of animals already known to have been there. This he attributes to the imperfection of our lift of animals, especially those of the unknown parts of the earth; adding, that the most expert mathematician at this day could not affign the proportion of a veffel better accommodated to the purpose than is here done: and hence he finally concludes, that the capacity of the ark, which had been made an objection against Scripture, ought to be esteemed a confirmation of its divine authority; since, in those ruder ages, men, being lefs verfed in arts and philosophy, were more obnoxious to vulgar prejudices than now; fo that, had it been a human invention, it would have been contrived, according to those wild apprehensions which arife from a confused and general view of things, as much too big as it had been represented too little.

But it must be observed, that, besides the places requisite for the beasts and birds, and their provisions, there was room required for Noah to lock up household utensils, the instruments of husbandry, grains, and seeds to sow the earth with after the deluge; for which purpose it is thought that he might spare room in the third story for 36 cabbins, besides a kitchen, a hall, sour chambers, and a space about 48 cubits in length to

walk in.

Plate LII.

fig. 2.

Ask of the Covenans, a small chest or coffer, three feet nine inches in length, two feet three inches in breadth, and two feet three inches in height, in which were contained the golden pot that had manna, and Aaron's rod, and the tables of the covenant. This coffer was made of shittim wood, and covered with a lid, which was made of solid gold. The ark was reposited in the holiest place of the tabernacle. It was taken by the Philistines, and detained 20, some say 40 years, at Kirjath-jearim; but the people being afflicted with emerods on account of it, returned in with divers presents. It was afterwards placed in the temple.

The lid or covering of the ark was called the propinatory or mercy-feat; over which were two figures placed called Cherubims, with expanded wings of a peculiar form. Here the Schechinah rested both in the tabernacle and temple in a visible cloud: hence were issued the Divine oracles by an audible voice; and the high priest appeared before this mercy-seat once every year on the great day of expiation; and the Jews, wherever they worshipped, turned their faces towards

the place where the ark flood.

In the ferond temple there was also an ark, made of the same shape and dimensions with the first, and put in the same place, but without any of its contents and peculiar honours. It was used as a representative of the former on the day of expiation, and a repository of the original copy of the holy Scriptures, collected by Ezra and the men of the great synagogue, after the captivity. And in imitation of this, the Jews to this day have a kind of ark in their fynagogues, wherein their facred books are reposited. This they call aron. Leo of Modena gives a description thereof in his Account of the Customs and Ceremonies of those of his Nation. "The Jews (fays he), in the eastern fide of their fynagogues, have an ark, or armory, called aron, in memory of the ark of the covenant. In this are preserved the five hooks of Moses, written on vellum, with ink made on purpole," &c. Some have supposed that the figure of this ark, is still remaining on the triumphal areh of Titus at Rome; though Villalpandus and others, with greater reason, are of opinion, that it is the table of shew bread. Prideaux's Con. Vol. I. p. 209. Tertullian calls this ask Armarium Judaicum; whence the phrase, to be in the armory of the synagogue, q. d. in the number of canonical writings.

A cheft or coffer, very nearly refembling the Jewish ark, and called the house of the God, was found in Huaheine, one of the islands in the southern sea. Mr Banks could obtain no other information concerning it than what the name imports. Hawkesworth's Account, &c.

Vol. II. p. 252.

ARKLOW, a fea port town of Ireland, in the county of Wicklow, and province of Leinster. W.

Long. 6. 15. N. Lat. 52. 55.

ARLES, a city of Provence in France, seated on the east side of the Rhone, on a hill, whose declivity is towards the north. It is an archbishop's see; and is celebrated for its antiquities both within and without the city. Those of which any remains are now to be seen are the amphitheatre, the obelisk, the elysian fields, the sepulchres, columns with their capitals, busts, pedestals, aqueducts, with some remains of the capitol, and the temples of their gods. The other ancient monuments are entirely destroyed. Under the amphitheatre, in 1651, they sound the statue of Venus, which was worshipped by this city; and has been since carried to the castle of Versailles. It is a masterpiece which will always be admired by connoisseurs.

The amphitheatre is one of the most remarkable pieces of antiquity. It was built by the Romans, but the time is unknown, though some say by Julius Cæsar. It is of an eval form, and about 400 yards in circumference, and the front is 34 yards in height. The middle, called the Arena, is 142 yards wide and 104 broad. The porticoes or piazzas are three stories, built with stones of a prodigious size. Each of them consists of 60 arches, which still remain; and the walls are of sur-

prifing thickness, but gone to decay.

The obelisk is the only one of this kind to be seen in France. It seems to be one of the forty brought from Egypt to Rome, because it is of the same oriental granite with them. They are generally full of hieroglyphic characters; but this is quite smooth. In 1675, it was found in a private garden near the walls of the city, not far from the Rhone. It consists of one piece; and is 52 feet high, and 7 in diameter at the base. It

Askers 'le now supported with four lions made of bronze; and on the top a blue ball is placed, with the arms of irmacales. France, and over that a fun.

The Pagans burying place called the Elyfian Fields, is without the city, upon an agrecable hill, divided into two parts. The first, called Moulaires, has very few tombs, they having been broken to build the walls of gardens, which are made in that place. The fecond, called Eliscamp, contains a great number. Those of the Pagans have the letters D. M. which fignifies Diis Manibus. Those of the Christians have a cross. Pieces of coin of gold, filver, and bronze, are found here; as also urns, lamps, and cups, without number.

Here is a royal academy of sciences, consisting of thirty members, who must be natives, gentlemen, and inhabitants of the city. It enjoys the same privileges as that at Paris. Arles is furrounded with marshy land, which renders the air full of vapours, and makes it not very wholesome. Long. 4. 48. E. Lat. 43. 40.

ARLEUX, an ancient town of the Netherlands, in Cambresis, with a cattle. It was taken by the French in 1645, and retaken by the Allies in 1711; but the I rench got possession again the same month. E. Long. . 16. N. Lat. 59. 17.

ARLON, an ancient town of the Netherlands, formerly a strong place, but now difmantled. It belongs to the house of Austria. E. Long. 15. 50. Lat. 49. 4.

ARM, a part of the human body, terminating at one end in the shoulder, and at the other in the hand. Sec Anatomy, Nº 48.

ARM, among sportsmen, is applied to a horse, when by preffing down his head, he endeavours to defend himself against the bit, to prevent his being checked by it. The remedy is, to have a wooden ball covered with velvet, or other matter, put on his chaul, which will so press him between the jaw bones as to prevent, his bringing his head fo near his breaft.

ARM, in geography, is used for the branch of a sea or river. Italy and Sicily are only parted by an arm of the sea. St George's arm in the Mediterranean is

the Thracian Bosphorus. ARM is also used figuratively for power. The secular aim is the lay or temporal authority of a fecular

judge; to which recourse is had for the execution of the fentences passed by ecclesiastical judges.

The church sheds no blood: even the judges of inquisition, after they have found the person guilty, furrender him to the secular arm. The council of Antioch, held in 341, decrees, that recourse be had to the fecular arm to repress those who refuse obedience to the church: for fecular arm, they here use exterior power.

ARM, in respect of the magnet. A loadstone is said to be armed, when it is capped, cased, or set in iron or steel, in order to make it take up the greater weight, and also to distinguish readily its poles. See MAGNETISM.

ARMACALES, a river of Babylon (Abydenus); called Fossa Regia, the Royal Trench or Cut (Polybius); the Royal River (Ptolemy); Almarchur (Pliny); Nagrmaliha (Ammian); a factitious channel or cut, made by Nabuchadonofor, and a horn or branch of the Euphrates, (Abydenus). The Euphrates naturally divides into two channels, one passing through Babylon, the other through Seleucia, and then falls into the Tigris; the factitious channel between these two is the Armads. Royal River; which mixes with the Tigris, a great deal lower down than Seleucia, at Apamea, (Ptolemy).

M

ARMADA, a Spanish term, fignifying a fleet of men of war. The armada which attempted to invade England in the time of Queen Elizabeth, is samous in

This armada, to which the Spaniards, in confidence of success, gave the name of Invincible, consisted of 150 ships, most of which were greatly superior in strength and fize to any that had been feen before. It had on board near 20,000 foldiers, and 8000 failors, befides 2000 volunteers of the most distinguished families in Spain. It carried 2650 great guns, was victualled for half a year, and contained such a quantity of military stores, as only the Spanish monarch, enriched by the treasures of the Indies and America, could supply. The troops on board were to be joined by 34,000 more which the duke of Parma had affembled in the neighbourhood of Nieuport and Dunkirk. For transporting thefe, he had, with incredible labour, provided a great number of flat bottomed vessels, and had brought sailors to navigate them from the towns in the Baltic. Most of these vessels had been built at Antwerp; and as he durft not venture to bring them from thence by sea to Nieuport, lest they should have been intercepted by the Dutch, he was obliged to fend them along the Scheld to Ghent, from Ghent to Bruges by the canal which joins these towns, and from Bruges to Nieuport by a new canal which he dug on the present occasion. This laborious undertaking, in which several thousand workmen had been employed, was already finished, and the duke now waited for the arrival of the Spanish fleet; hoping, that as foon as it should approach, the Dutch and English ships which cruised upon the coast would retire into their harbours.

When the news reached England that this mighty fleet was preparing to fail, terror and consternation universally seized the inhabitants. A fleet of not above 30 ships of war, and those very small in comparison, was all that was to oppose it by sea. All the commercial towns of England, however, were required to furnish ships for reinforcing this small navy. The citizens of London, instead of fifteen vessels, which they were commanded to equip, voluntarily fitted out double the number; and the gentry and nobility equipped 43 ships at their own charge. Lord Howard of Effingham was admiral; and under him ferved Drake. Hawkins, and Frobisher, all of them renowned as seamen of courage and capacity. The principal fleet was stationed at Plymouth. A smaller squadron, confifting of 40 veffels, English and Flemish, was commanded by Lord Seymour fecond fon of protector Somerfet, and lay off Dunkirk in order to intercept the

duke of Parma.

The land forces of England were more numerous than those of the enemy, but inferior in discipline and experience. An army of 20,000 men was disposed in different bodies along the fouth coaft, with orders to ritire backwards and waste the country, if they could not prevent the Spaniards from landing; 22,000 foot and 1000 horse, under the command of the carl of Leteefter, were stationed at Tilbury, in order to defend the capital; and the principal army confifting of 34,000 foot and 2000 hoise, commanded by Lord

Hunfdon,

Armada. Hunfdon, was referved for guarding the Queen's perfon, and appointed to march whitherfoever the enemy should appear. These armies, though all the Spanish forces had been able to land, would possibly have been fufficient to protect the liberties of their country. But as the fate of England, in that event, must depend on the issue of a single battle, all men of serious reflection entertained the most awful apprehensions of the shock of at least 50,000 veterans, commanded by experienced officers, under so consummate a general as the duke of Parma. The Queen alone was undaunted. She issued all her orders with tranquillity, animated her people to a steady resistance, and employed every resource which either her domestic situation or her foreign alliances could afford her. She even appeared on horseback in the camp at Tilbury; and riding through the lines, discovered a cheerful and animated countenance, exhorted the foldiers to remember their duty to their country and their religion, and professed her intention, though a woman, to lead them herfelf into the field against the enemy, and rather perish in battle than furvive the ruin and flavery of her people. "I know (faid she, intrepidly) I have but the weak and feeble arm of a woman; but I have the heart of a king, and of a king of England too!" The heroic spirit of Elizabeth communicated itself to the army and every man resolved to die rather than desert his station.

> The Spanish armada was ready in the beginning of May; but its failing was retarded by the death of the marquis of Santa Croce the admiral, and that also of the vice-admiral the duke of Paliano. The command of the expedition was therefore given to the duke of Medina Sidonia, a man entirely unexperienced in sea affairs. This promotion, in some measure, served to frustrate the delign, which was also rendered less succefsful by fome other accidents. Upon leaving the port of Lisbon, the armada next day met with a violent tempest, which sunk some of the smallest of their shipping, and obliged the fleet to put back into the harbour. After some time spent in resitting they put again to sea. Being descried by Fleming, a Scottish pirate, who was rowing in those seas, he immediately failed towards the English sleet, and informed the admiral of their approach. Effingham had just time to get out of port when he law the Spanish armada coming full fail towards him, disposed in the form of a crescent, and stretching the distance of seven miles from the extremity of one division to that of the other. The English admiral considering that the Spaniards would probably be much superior to him in close fight, by reason of the size of their ships and the number of their troops, wifely resolved to content himself with harassing them in their voyage, and with watching attentively all the advantages which might be derived from storms, cross winds, and such like fortuitous accidents. It was not long before he discerned a favourable opportunity of attacking the vice-admiral Recaldo. This he did in person; and on that occasion displayed fo much dexterity in working his ship, and in loading and firing his guns, as greatly alarmed the Spaniards for the fate of the vice-admiral. From that time they kept much closer to one another; notwithstanding which, the English on the same day attacked one of the largest galeasses. Other Spanish ships came Vol. II. Part I.

up in time to her relief; but in their hurry one of the Arnada. principal galleons, which had a great part of the treafure on board, ran foul of another thip, and had one of her masts broken. In consequence of this missortune she fell behind, and was taken by Sir Francis Drake; who on the same day took another capital ship, which had been accidentally set on sire.

Several other rencounters happened, and in all of them the English proved victorious, through the great advantage which they derived from the lightness of their ships, and the dexterity of the sailors. The Spaniards in that age did not infliciently understand nautical mechanics, to be able to avail themselves of the unufual magnitude of then thips. The English fail d round them, approached or retired, with a velocity that filled them with amazement, and did infinitely greater execution with their cannon; for while every that of theirs proved effectual, their thips fuffered very little damage from the enemy, whose guns were planted too high, and generally spent their force in air.

The Spaniards, however, full continued to advance till they came opposite to Calais; there the duke de Medina having ordered them to cast anchor, he fent information to the duke of Parma of his arrival, and entreated him to haften the embarkation of his forces. Farnese accordingly began to put his troops on board. But at the fame time he informed Medina, that agreeably to the king's inflructions, the veffels which he had prepared were proper only for transporting the troops, but were utterly unfit for fighting; and for this reason, till the armada were brought still nearer, and the coast cleared of the Dutch ships which had blocked up the harbours of Nicuport and Dunkirk, he could not flir from his present station, without exposing his army to certain ruin, the confequence of which would probably be the entire loss of the Netherlands.

In compliance with this request, the armada was ordered to advance; and it had arrived within fight of Dunkirk, between the English flect on the one hand, and the Dutch on the other, when a fudden calm put a stop to all its motions. In this situation the three fleets remained for one whole day. About the middle of the night a breeze sprung up; and Lord Howard had recourfe to an expedient which had been happily devised on the day before. Having filled eight ship. with pitch, fulphur, and other combustible materials, he fet fire to them, and fent them before the wind against the different divisions of the Spanish fleet.

When the Spaniards beheld thefe thips in flames approaching towards them, it brought to their remembrance the havock which had been made by the fire ships employed against the duke of Parma's bridge at the fiege of Antwerp. The darkness of the night increased the terror with which their imaginations were overwhelmed, and the panic flew from one end of the fleet to the other. Each crew, auxious only for their own prefervation, thought of nothing but how to efcape from the present danger. Some of them took time to weigh their anchors, but others cut their cables, and fuffered their ships to drive with blind precipitation, without confidering whether they did not thereby expose themselves to a greater danger than that which they were so folicitous to avoid. In this confusion the T t fhips

Asmada ships ran foul of one another; the shock was dreadful, irmadilia. and feveral of them received fo much damage as to be rendered unfit for future use.

When day light returned, Lord Howard had the fatisfaction to perceive that his stratagem had fully produced the defired effect. The enemy were still in extreme diforder, and their ships widely separated and dispersed. His sleet had lately received a great augmentation by the ships sitted out by the nobility and gentry, and by those under Lord Seymour, who had left Justin de Nassau as alone sufficient to guard the coast of Flanders. Being bravely seconded by Sir Francis Drake and all the other officers, he made halte to improve the advantage which was now prefented to him, and attacked the enemy in different quarters at the same time with the utmost impetuosity and ardour. The engagement began at four in the morning, and lasted till six at night. The Spaniards displayed in every rencounter the most intrepid bravery; but, from the causes already mentioned, they did very little execution against the English; while many of their own thips were greatly damaged, and twelve of the largest were either run aground, or funk, or compelled to furrender.

It was now evident that the purpose of the armada was utterly frustrated. The Spanith admiral, after many unfuccessful rencounters, prepared therefore to make his way home; but as the winds were contrary to his return through the Channel, he refolved to take the circuit of the illand. The English fleet followed lom for fome time; and had not their ammunition fallen short, through the negligence of the public offices in supplying them, they had obliged the armada to furrender at discretion. Such a conclusion of that vain-glorious enterprise would have been truly illustrious to the English, but the event was scarce less fatal to the Spaniards. The armada was attacked by a violent storm in passing the Orkneys; and the ships, having already loft their anchors, were obliged to keep at fea, while the mariners, unaccustomed to hardships, and unable to manage fuch unwieldy veffels, allowed them to drive on the Western isles of Scotland, or on the coast of Ireland, where they were miserably wrecked. Not one half of the fleet returned to Spain, and a flill finaller proportion of the foldiers and feamen; yet, Philip, whose command of temper was equal to his ambition, received with an air of tranquillity the news of so humbling a disaster. " I fent my fleet (said he) to combat the English, not the elements. God be praised that the calamity is not greater!" This calamity, however, was fenfibly felt all over Spain, and there was scarcely a single family of rank in the kingdom that did not go into mourning for the death of fome near relation; infomuch that Philip, dreading the effect which this universal face of forrow might produce upon the minds of the people, imitated the conduct of the Roman senate after the battle of Canna, and published an edict to abridge the time of public

ARMADILLA, in Spanish America, denotes a squadron of men of war, to the number of fix or eight from twenty-four to fifty pieces of cannon, which the king maintains, to prevent foreigners from trading with the Spaniards and the Indians, both in time of war and peace.

The vessels of this armadilla are those that have been Armadilla so much talked of, under the name of guarda coffas. Armagh They have even power to take all Spanish merchant ships they meet with on the coast that have not licenfes from the king.

The South sea has its armadilla as well as the North fea. The ordinary abode of the former are at Calao, a port of Lima; that of the latter at Carthagena.

ARMADILLO, in zoology, a fynonyme of the da-

fypus. See DASYPUS.

ARMAGEDDON, a place spoken of in the Revelation (xvi. 16.), which literally fignifies the Mountain of Mageddon or Megiddo, a city fituated in the great plain at the foot of Mount Carmel, where King Josiah received his mortal wound in the battle against Necho king of Egypt. At Armageddon, the three unclean spirits, coming out of the dragon's mouth, shall gather together the kings of the earth to the battle of the great day of God Almighty (Rev. xvi. 13, 14.) The word armageddon, according to Mr Poole, does not fignify any particular place, but is here an allusion, as some think, to that of Megiddo, mentioned Judges v. 19. where Barak overcame Sifera with his great army, and where Josiah was slain (2 Kings xxiii. 30.) Others translate this word, the Mountain of the gospel, and others, the Mountain of apples or fruits.

ARMAGH, a county of Ireland, bounded by Louth on the fouth; Lough-neagh, on the north; Tyrone and Monaghan, on the west; and Down, m part, on the east, from which it is separated by the river Newry. It is in length 32 miles, in breadth 17; and is divided into five baronies, containing about 170,620 acres. Both the air and foil are good, especially the latter, which is said to be the richest in Ireland; only there is a certain tract in it called the Fewes, that is, billy and barren. The members it fends. to parliament are fix, viz. two for the city of Armagh, two for the county, and two for the borough of Charle-

Armagh, flanding near the river Kalin, gives name to the county, and is the fee of the primate of all Ireland. -It is faid to have been founded by St Patrick in the fifth century; and in 1142, it was constituted an archbishoprick, together with Dublin, Cashel, and Tuam, by Cardinal Papyreo, with the confent of the king, dukes, bishops, abbots, and states of Ireland. This Papyreo was fent into Ireland by Pope Eugenius, to reform the abuses that had crept into the church discipline of that country. Here was anciently a famous monaftery built by St Columba, or Columbanus, about the year 610. The cathedral was often burnt, but as often rebuilt and enlarged, and particularly by Patrick Scanlain, about 1262. His successor Nicholas, fon of Molissa, besides books, rich ecclesiastical vestments, and other things, bestowed on it an annual penfion of twenty marks. He appropriated also to his see the manor of Dromyskin. He died the toth of May, 1303. This town was first subjected to the English. by John de Courcy; but afterwards entirely destroyed by Tir Oen, or O'Neal, in Queen Elizabeth's time. However, it was afterwards recovered, rebuilt, and garrifoned by the English.

The fee of Armagh is valued in the king's books, by an extent taken anno 30th Henry VIII. at 1831. 17s. 5 d. Irish money per annum, which amounts to

Armagnae 1371. 18s. old. (the difference between Irish and Sterling money being at that time one-fourth). But by Armed. an extent returned in the 15th of James I. it is valued at 400l. sterling per annum, and pays so much first fruits to this day. It is reputed to be worth annually 8000l. The chapter of Armagh is composed of five dignitaries and four prehendaries, who have voices in every capitular act. The dignitaries are thus ranked, viz. a dean, chanter, chancellor, treafurer, and archdeacon. There are also eight vicars choral, and an organist, attendant on the service of the cathedral. The vicars choral were anciently fewer; and of the number only one priest. Primate Marsh added another priest, but without increasing the number of vicars. In the year 1720, Primate Lindsay obtained a new charter for enlarging the number of the faid vicars to eight, and laid out upwards of 4000l. on a purchase, in augmentation of the effate of the choir.

ARMAGNAC, a province of Guienne in France, 55 miles in length and 40 in breadth; bounded on the east by the river Garonne, on the fouth by Bigorre and Bearn, on the west by Gascony, and on the north by Condomois and Agenois: Auch is the capital town. It is fertile in corn and wine, and carries on a confiderable trade in brandy, wool, and bonchre-

tin pears, which are excellent.

ARMAMAXI, in antiquity, a kind of Scythian chariots or carriages, composed of two wheels, varioufly adorned with crowns, shields, breastplates, and other spoils, carried in procession after the images of the gods and great men.

ARMAMENT, a large body of forces, raifed and provided with the furniture of war, either for land or

fea fervice.

ARMATURA, in a general fense, is the same with what we otherwise call armour.

ARMATURA is more particularly used in the ancient military art, for a kind of exercise, performed with missive weapons, as darts, spears, arrows, and the like. In this sense, armatura stands contradistinguished from palaria; the latter being the exercise of the heavyarmed, the former of the light-armed.

The armatura was practifed with great diligence among the Romans; they had their campidostores, on purpole to instruct the tyrones or young soldiers in it. Under it were included the throwing of the spear or javelin, shooting with bows and arrows, &c.

ARMATURA is also an appellation given to the sol-

diers who were light armed.

ARMATURA is also a denomination given to the soldiers in the emperor's retinue. Of these we find two schools, mentioned in the Notitia Imperii, called the armatura schiores and armatura juniores. Their commander was entitled tribunus armaturarum.

ARMED, in the sea language. A cross bar shot is faid to be armed, when some rope yarn or the like is rolled about the end of the iron bar, which runs through the shot.

ARMED, in heraldry, is used when the horns, feet, beak, or talons, of any beatt or bird of prey, are of a

different colour from the rest of their body.

ARMED Ship, a vessel occasionally taken into the fervice of the government in time of war, and employed to guard fome particular coast, or attend on a fleet. She is therefore armed and equipped in all respects like a ship of war, and commanded by an offi- Armene, cer of the navy, who has the rank of master and com- Armenia mander. All ships of this fort are upon the establishment of the king's floops, having a licutenant, mafter, purfer, furgeon, &c.

ARMENE, or ARMINA, anciently a hamlet of Paphlagonia, (Ptolemy). The inhabitants encompassed it with a wall, because of the coldness of the place, imagining by that means to render it warmer. But this proving ineffectual, gave rife to the proverb Armenen muro cingere, used to express some egregious folly.

ARMENIA, a country of Asia, anciently divided into Armenia Major and Minor. Armenia Major, according to Strabo, was bounded on the fouth by Mount Taurus, which separated it from Mesopotamia; on the east, by the two Medias; on the north, by Iberia and Albania, or rather that part of Mount Caufacus which furrounds them both; and on the west, by Armenia Minor, or the mountains Paryadres, some Pontic nations, and the Euphrates. The most considerable cities were Artaxata, Tigranocerta, and Thedosiopolis. -Armenia Minor was bounded on the east by the Euphrates; on the fouth by Mount Taurus, which feparated it from Cilicia; on the west and north, by a long chain of mountains called in different places Mons Scordifeus, Amanus, and Antitaurus, by which it was separated from Cappadocia.

Whence this tract received the name of Armenia is not determined. The Greeks suppose it to be so called from one Armenus, who attended Jason in the Argonautic expedition, and afterwards fettled in this country. Others, transforming Armenia into Aramia, derive its name from Aram the fon of Shem, or from one of the kings of Armenia bearing that name. Bochart imagines it to be a contraction or compound of Aur, a Hebrew word fignifying a "mountain," and Mini fignifying " metal," and which was the name of a province of Armenia mentioned by the prophet Jeremiah.

Herodotus derives the ancient Armenians from the Phrygians, by reason that several Phrygian words were crept into the ancient Armenian language. But Strabo reckons them to have been originally Syrians, which Bochart looks upon to be the most probable opinion.

Armenia is faid to have been very early advanced to the honour of a kingdom. Perofus makes one Sytha the first founder of this monarchy, whose successor Bardanes, he fays, was driven out by Ninus king of Affyria. Plutarch mentions one Araxes king of Armenia, who in a war with the Persians, being assured of success by an oracle, provided he sacrificed his two daughters, caused the two daughters of one Miesalcus, a nobleman of his court, to be facrificed in their stead, flattering himfelf that he thereby complied with the oracle. But Miesalcus did not fail to revenge the death of his own daughters by putting the king's two daughters to death, and purfued himself so closely, that he was drowned in attempting to swim across the Araxes, which was then called Helmus.

The Armenians were in process of time subdued by the Medes, to whom Astyages made them tributaries, but allowed them to be governed by their own kings; but on the dissolution of the Median empire by Cyrus, the kingdom was reduced to the form of a province, and they were governed by Persian prefects or lieutenants. On the destruction of the Persian empire by

Tt2

Alexander

Armenia. Alexander the Great, Armenia fell into the hands of the Macedonians; to whom it continued subject till the beginning of the reign of Antiochus the Great. This prince having appointed two prefects, called Zadriades and Artanius, to govern Armenia, they excited the people to a revolt, and caused themselves to be proclaimed kings of the provinces over which they prefided. Antiochus being then very young, they were attended with fuccels beyond their expectation; which encouraged them to attempt the enlargement of their territories. Accordingly, invading the neighbouring countries, they took from the Medes the provinces of Caspiana, Phannitis, and Basoropida; from the Iberians Chorzena and Gogorena on the other fide of the Cyrus; from the Chalybes and Mossynæci, the provinces of Pareneta and Herexena, which bordered on Armenia Minor.

> On this occasion, the above-mentioned division of the kingdom into Armenia Major and Minor first took place. Artaxias became king of Armenia Major, and Zadriades of Armenia Minor; and this distinction subfifts even at this day.

> By whom Artaxias was fucceeded is not known; neither have we any account of the transactions of his reign, farther than that Antiochus led a powerful army against him and Zadriades, but without being able to recover a fingle province. Upon this he concluded a peace, defigning to fall upon them at a proper opportunity; but they having entered into alliance with the Romans, by that means fecured themselves in the possession of their kingdom. After this, Artaxias was defeated and taken prisoner by Antiochus Epiphanes; but fomehow or other, feems to have been reflored to his kingdom.

> From this time we meet with a chasm in the Armenian history for 70 years; during which all we know is, that Tigranes, the king's fon, was delivered up as an hostage to the Parthans; from whence it is plain, that the Armenians had been carrying on an unfuccessful war with that nation. On the news of his father's death, however, the Parthians fet the young king at liberty, having first obliged him to give up a confiderable part of his kingdom by way of ranfom.

> Tigranes, being thus reftored to his father's kingdom, was prevailed upon in the beginning of his reign to enter into an alliance with Mithridates Eupator against the Romans, whose power began to give jealoufy to all the princes of Asia. One of the articles of this treaty was, that Mithridates should have the cities and conquered countries, and Tigranes the captives and plunder. In confequence of this, Tigranes was to invade Cappadocia, which he had lately been obliged, by a decree of the senate of Rome, to give up to Ariobarzanes. But before either of the princes took the field, a marriage was folemnized with all possible magnificence, between Tigranes and Cleopatra the daughter of Mithridates.

> Immediately after the nuptials, Tigranes fet out on his intended expedition; and Ariobarzanes, on the first news of his march, ahandoned his kingdom and fled to Rome. Thus Tigranes, without fighting a stroke, enriched himself with the booty, and then proclaimed Ariarathes, Mithridates's fon, king of Cappadocia, to the universal satisfaction of the people.

> In the mean time, the Syrians being haraffed with

a long and intestine war of the Seleucidæ, invited Ti- Armenie granes to come and take possession of their country; which he accordingly did, and kept it for 18 years, till he was driven out by Pompey, and Syria reduced to the form of a Roman province: Encouraged by this fuccess, he next invaded Armenia Minor: defeated and killed King Artanes, who opposed him with a confiderable army; and in one campaign made himfelf master of the whole kingdom. From Armenia Minor he marched against the Asiatic Greeks, the Adiabenians, the Affyrians, and the Gordians, carrying all before him, and obliging the people wherever he came to acknowledge him fovereign. From this fecond expedition he returned home loaded with booty, which he foun after increased by the spoils of Cappadocia, invading that kingdom a fecond time at the instance of Mithridates, who had been obliged by the Romans to withdraw his forces from thence. From Cappadocia Tigranes, besides other booty, brought back into Armenia no fewer than 300,000 captives, having furrounded the country with his numerous forces in fuch a manner that none could escape. These, together with the prisoners he had taken in his two first expeditions, he employed in building the city of Tigranocerta, which they afterwards peopled.

In the mean time Mithridates, who had concluded a peace with the Romans for no other end than to gain time, fent a folemn embaffy to Tigranes, inviting him to enter into a fecond alliance against the common ene-This he at first declined; but in the end was prevailed upon by his wife Cleopatra to fend him confiderable supplies, though he never came heartily into the war, not caring to provoke the Romans, who on their part kept fair with him, taking no notice for the present of the supplies he had sent Mithridates. That unfortunate prince being foon after defeated by Lu-cullus, was forced to fly for shelter into Armenia, where he met with a very cold reception from his fonin-law, who would neither fee him, treat with him, nor own him as his relation; however, he promifed to protect his person, and allowed him in one of his castles a princely retinue, and a table suitable to his former condition.

Though this total overthrow of Mithridates might have opened the eyes of Tigranes, and made him oppose with all his might the growing power of the Romans, he foolishly left them to finish their conquest of Pontus, while he marched at the head of a very numerous army against the Parthians, with a design to recover from them the dominions they had formerly extorted from him before they fet him at liberty. These he cally retook; and not fatisfied with what formerly belonged to him, he added to them all Mcfopotamia, the countries that lay about Ninus and Arbela and the fruitful province of Mygdonia; the Parthians, though at that time a mighty people, flying everywhere before him. From Melopotamia Tigranes marched into Syria to quell a rebellion which had been raifed by Cleopatra furnamed Selene; who, after the death of her husband Antiochus Pius, reigned jointly with her sons in that part of Syria which Tigranes had not seized on. The malcontents were quickly reduced; and the queen herself was taken prisoner, and confined to the callle of Seleucia, where the was foon after put to death by the king's orders. From Syria Tigranes paf-

Armenia. fed into Phœnicia, which he subdued either entirely or in great part, spreading far and wide the terror of his arms, infomuch that all the princes of Asia, except those who were in alliance with the Romans, either in person or by their deputies, submitted and paid ho-

mage to the conqueror.

The king, having now subdued all Syria to the borders of Egypt, and being elated with a long course of victories and prosperous events, began to look upon himself as far above the level of other crowned heads. He assumed the title of King of kings, and had many kings waiting upon him as menial fervants. He never appeared on horseback without the attendance of four kings dreffed in livery, who run by his horse; and when he gave answers to the nations that applied to him, the ambaffadors flood on either fide the throne with their hands clasped together, that attitude being of all others then accounted among the orientals the greatest acknowledgment of vassalage and servitude. In the midst of all this haughtiness, however, he was unexpectedly visited by an ambassador from Lucullus the Roman general, who, without any ceremony, told him, that he came to demand Mithridates king of Pontus, who had taken refuge in his dominions, and, in case of his refusal, to declare war against him. Notwithstanding his high opinion of himself, Tigranes returned a mild answer to this message: in which, however, he refused to deliver up his father-in-law; and being highly provoked at Lucullus for not giving him the title of King of kings in his letter, he did not fo much as bestow upon him the title of general in his answer. In the mean time, being informed that Zarbienus king of the Gordians had entered into a private alliance with the Romans, he put him, his wife, and children to death; and then, returning into Armenia, received with the greatest pomp imaginable his fatherin-law Mithridates, whom till that time he had not admitted into his presence, though he had resided a year and eight months in his dominions. They had feveral private conferences; and at last Mithridates was fent back to Pontus with 10,000 horse, to raise there what disturbances he could.

Lucullus, on the other hand, hearing the king's refolution to protect Mithridates, immediately began his march for Armenia, at the head of only two legions of foot and 3000 horse, having left 6000 men in Pontus to keep that country quiet. Having passed the Euphrates without opposition, he detached two parties; one to beliege a city where he heard that Tigranes's treasure and concubines were kept; and the other under Sextilius, to block up Tigranocerta, in order to draw the king to a battle. But Tigranes, after having put to death the scout that brought him the first intelligence of the approach of the Romans, made towards Mount Taurus, which he had appointed for the place of the general rendezvous. The Roman general then despatched Muræna in pursuit of the king; who, having overtaken him in a narrow pass, defeated him, and, belides all the baggage, carried off a great many prisoners, the king himself having sled in the beginning of the skirmish. After this, he sent out several parties to scour the country, in order to prevent the innumerable forces of Tigranes from joining into one body. This, however, he was not able to effect; Tigranes was joined by fuch numbers of Gordians, Medes, Adiabenians, Albanians, Iberians, &c. that, before he left Mount

Taurus, his army confided, according to Plutarch, of Armenia 150,000 foot armed cap-a-pee, 35,000 pioneers, 20,000 archers and flingers, and 55,000 horse.

Lucullus was fo far from being difmayed at this formidable army, that the only fear he had was left the king should follow the advice of Mithridates, which was, not to engage the Romans, but, by ravaging the country, differes them for want of provisions. In order to draw him to a battle, therefore, he formed the fiege of Tigranocerta, imagining that Tigranes would never fuffer that fine city to be taken without making an attempt to relieve it. The event fully answered his expectations: Tigranes having called a council of war, it was unanimously resolved to attack the Romans; and Taxilis, whom Mithridates fent to diffuade the king from venturing a battle, was in danger of lofing his head on account of the advice he gave. The Roman general, finding Tigranes disposed to come to an engagement, left Muræna with 6000 men to carry on the fiege, while he himfelf marched against the king's vast army with only 10,000 men, according to fome, and the highest computations make them no more than The Romans were at first greatly disheartened; but being encouraged by Lucullus, they immediately broke the Armenian army, who betook themfelves to flight almost at the first onset. The Romans purfued them till night, making a most terrible slaugh-Plutarch informs us, that of the Armenians 100,000 foot were killed, and that very few of the cavalry escaped; whereas of the Romans only five men were killed and 100 wounded. Antiochus the philosopher mentioning this battle, fays, that the fun never beheld the like: and Livy, that the Romans never fought to such a disadvantage; the conquerors not amounting to a twentieth part of the conquered. Tigranes in his flight having met with his for in as for-lorn a condition as himfelf, religned to him his royal robes and diadem, defiring him to shift for himself and fave those royal enfigns. The young prince delivered them to a trully friend, who, being taken by the Romans, configued them to Lucullus.

While the king was making his escape after this terrible overthrow, he was met by Muhridates, who was marching to his affiltance at the head of a confiderable The king of Pontus cheered up his fon-in-law as well as he could, and encouraged him to continue the war: adviting him, instead of fruitlessly bewailing the present disaster, to rally his troops, raise new supplies, and renew the war, not questioning but that in another campaign he might repair all the loffes he had fullained: but while the two kings were confulting upon these matters, Lucullus made himself master of Tigranocerta. From this city he marched into the small kingdom of Gordyene, where he celebrated, with the utmost pomp, the obsequies of King Zarbienus, whom Tigranes had put to death, lighting the funeral pile with his own hands. In this kingdom, befides immenfe fums of gold and filver, he met with fuch store of provisions as enabled him to carry on the war with-

out putting the republic to any charge.

The two kings, having levied new forces, appointed their troops to rendezvous in the spacious plains on the other fide of Mount Taurus; whereupon Lucullus, leaving Gordvene, and paffing by Mount Taurus, encamped close by the enemy. Several skirmishes happened for fome time between the two armies without

Armenia, any confiderable advantage; but Lucullus could by no means draw them to a general engagement. Upon this he decamped, as if he defigned to march to Artaxata and lay fiege to that place, where Tigranes had left his wife and children, with great part of his treasures. He had scarce formed his camp when the enemy appeared, and fat down close by him. Lucullus did not allow them to fortify their camp, but immediately attacked them, and having put them to flight after a faint refistance, pursued them all night with great flaughter, took most of the chief officers prisoners, and returned the next day loaded with bootv.

The Roman foldiers now, finding the cold very fevere, though it was no latter in the year than the autumnal equinox, requested their general to allow them to retire into winter quarters. This request he rejected with indignation; upon which they mutinied. Lucullus did all he could to perfuade them to continue in their duty; and prevailed so far that they consented to lay fiege to Nisibis in hopes of booty. This place they took; and Lucullus, to the great satisfaction of his troops, took up his winter quarters there. The next year, however, his forces again mutinied, accufing him of amassing immense wealth for himself; and throwing their empty purses at his feet, told him, that as he enriched himself alone, he might carry on the war by himself. He endeavoured to appeale them as much as possible; but the sedition being fomented by a party who favoured Pompey the Great, at that time assiring to the command of Lucullus's army, the latter found himself obliged to sit still and see Mithridates and Tigranes overrun Cappadocia, and recover all Armenia and great part of Pontus. They would have gained much greater advantages, had not a fon of Tigranes taken arms against his father, and obliged him to divide his troops. The father and fon coming to a pitched battle, the latter was defeated, and forced to fave himself in Parthia, where he persuaded Phraates, king of that country, to affift him with a numerous army against his father. Phraates having laid siege to Artaxata, Tigranes the elder was obliged to hide himfelf in the mountainous parts of his kingdom; upon which the king of Parthia returned home. Of this Tigranes the father being apprized, he immediately abandoned the fastnesses of the mountains; and falling upon his fon at Artaxata, dispersed the rebels with great flaughter; and entered his metropolis in triumph. Tigranes the fon first sled to Mithridates; but finding him reduced to great straits, having been overcome a few days before, with the loss of 40,000 men, by Pompey, he went over to the Romans, and led them into Armenia against his father as an ally of Mi-

Tigrames, being now quite dispirited, and unable to make head against the Romans, resolved at once to fubmit. Accordingly he waited on Pompey in his camp, and having delivered his fword to two lictors. profrated himself before him, and laid his diadem at his feet. Pompey, however, gave him a gracious reception, restored him the kingdom of Armenia, but fined him of 6000 talents for making war on the Roman people without cause. As the king had appealed to the Roman general for justice against his son, Pompey heard both parties the next day, and made the fon

governor of Gordycne and Sophene; but the treasures Armenia. that were kept in the latter he adjudged to his father, because without them he could not pay the fine. The fon, being thus disappointed, endeavoured first to make his escape, and afterwards, by private messengers, solicited the inhabitants not to deliver up the treasures to his father. This being taken very much amifs by Pompey, he caused him to be kept in irons; and even then he found means to stir up Phraates king of Parthia, whose daughter he had married, against the Romans, and to form a conspiracy against his father's life; whereupon Pompey fent him in chains to Rome, where he was kept prisoner in the house of L. Flavius a senator, till the tribuneship of P. Clodious, who, being bribed with a large fum of money, fet him at liberty

in spite of Pompey and the senate.

Tigranes being now thoroughly humbled, willingly yielded to the Romans, Cappadocia, Syria, Cicilia, and that part of Phoenicia which he possessed, contenting himself with his paternal kingdom; and not only paid the fine laid upon him, but made large prefents to Pompey, and all the officers of his army, which procured him the title of the friend and ally of the Roman people. He afterwards entered into a war with Phraates king of Parthia, by whom he was overcome, and would have been driven out of his kingdom, had not a peace been brought about by the mediation of Pompey. He ever after cultivated a ftrict friendship with the Romans; infomuch that he not only refused to receive Mithridates, who fled to him after he had been routed by Pompey near Mount Stella, but even offered a reward of 100 talents to any one that would put him to death. His fecond fon also, by name Sariaster, took up arms against him; but by the assistance of the Romans, that rebellion was foon quelled. He died in the 85th year of his age; and was succeeded by his son Artuasdes, called by Josephus Artabazes, by Orofius Artabanes, and by others Artoadifles.

From this time to the time of Trajan, Armenia was governed by its own kings; but as they were plainly vallals to the Romans, though they did not take that title till the reign of the emperor Nero, their history falls to be confidered under that of the Romans.

By Trajan the kingdom of Armenia Major was reduced to the form of a Roman province; but it foon recovered its liberty, and was again governed by its own kings in the reigns of Constantine the Great, and his fuccessor, to whom the kings of Armenia were feudatories. In the reign of Justin II. the Saracens subdued and held it till the irruption of the Turks, who possessed themselves of this kingdom, and gave it the name of Turcomania. The Turks, after the reduction of Armenia, invaded Persia, and other countries subiect to the emperors of the east; which gave the Armenians an opportunity of shaking off the Turkish yoke, and fetting up kings of their own, by whom they were governed till the country was again subdued by Occadan, or, as some style him Heccata, the son of Cingis, and first cham of the Tartars. Neither was the conquelt of Armenia by the Tartars so absolute as to extirpate the race of their kings; feeing we read of Haithon, furnamed the Armenian, reigning some time after, and going in person to treat with Mungo, the great cham of Tartary, of the concerns of his kingdom; and in our chronicles we find mention made of Armenia. Leo king of Armenia, who, in the reign of Richard 'II. came into England to fue for aid against the Turks, by whom he had been driven from his kingdom. In the year 1472 of the Christian era, Ussan Cassanes king of Armenia fucceeding to the crown of Perfia, made Armenia a province of that empire; in which flate it continued till the year 1522, when it was subdued by Selim II. and made a province of the Turkish empire. Some fay that Selim I, reduced it on his return from Persia, where he had gained a complete victory over the great Sophi Ismael. But Sansovin assures us, that in the reign of Selim I. who died in 1520, both the Leffer and Greater Armenia had their own kings; and adds, that Sclim caused the head of the king of the Leffer Armenia to be cut off and fent to Venice as a mark of his victory. We read nowhere else of any kings of Armenia after it became a province of Persia. Be that as it will, the Turkish annals cited by Calvifius inform us, that Selim II. conquered Armenia in 1522, fince which time it has ever continued subject to the Turks, except the eathern part, which the Persians are masters of to this day.

> Concerning Armenia Minor, we find very little recorded, except what has been already mentioned, and what falls under the Roman history. It was made a Roman province by Vespasian, continued so till the division of the empire, when it was subjected to the emperors of the east; and, on the decline of their power, was fubdued first by the Persians, and afterwards by the Turks, who gave it the name of Genech, and have kept it ever fince.

> This country is still divided into the Great and Small. Great Armenia comprehends what is now called Turcomania. It has Georgia on the north, from which it is separated by high mountains; the river Euphrates on the west; Diarbeker, Curdistan, and Aderbijan, on the fouth; and Shirvan on the east. The chief towns in that part of Armenia belonging to Turkey are Arzum the capital, near the springs of the Euphrates, a large city and a great thoroughfare for the caravans between Turkey and Perlia; Kara, a frong city, head of the government of the same name; Bayazid, a republic of Curds, near Mount Ararat: Baha, another republic of the same; and Van or Wan, on the lake Van, the head of a government of the fame name; with other towns of less note. That part of Armenia subject to Persia is chiefly contained in the province of Aran, in which are several fine towns; as, Erivan or Rivan, the capital of the whole; Ganjals, one of the finest cities in Persia, in the north of the province, near the Kur; Kapan, on the fouth fide, near the Aras; besides Naksivan, Atlabad Julsa, Ordabad, Baylakan or Pilkan, on the Aras; Berdah and Shilkah on the Kur.

> The country in general is full of mountains and valkys, lakes, and rivers; particularly the country about the Three Churches, near Erivan, is admirably fine, being full of rivulets, which render it extremely fruitful. Belides great quantities of all forts of grain, here are fields of a prodigious extent covered with tobacco: but it is not a native of the place, though supposed by fome to be the terrestrial paradife; for it all came originally from America. The rest of the country produces rice, cotton, flax, melons, and grapes : in short, there is nothing wanting but olives; which is by fome

thought to prove that the ark could not rest on Mount Armenia. Ararat, because the dove brought an olive branch in her mouth, and this tree never leaves a place where it once grew. It feems, however, to have been otherwise anciently; for Strabo tells us, that the olive grew in Gogarene, a province of Armenia. They get oil to burn from the ricinus, and use linseed oil in the kitchen. The water melons are as cool as ice in the hottest day, and melt in the mouth; the best are produced in the falt lands, near the Three Churches and the river Aras. After rain, the sea salt lies in crystals upon the fields, and even crackles under the feet. About ten miles from the Three Churches, in the road to Teflis, there are pits or quarries of fossil falt, which yield enough to supply all Persia, without being exhausted: they cut it into large pieces like stone, and each buffalo carries two of them; the mountain from whence it is dug is nothing but a mass of falt, which appears like a rock of filver when the fun thines on the places not covered with earth.

This country has been remarkable for its extreme cold from the remotest antiquity; Sir John Chardin tells us, that he found ice in the rivulets in the mornings even of the month of July. In many places, also, if they had not the convenience of watering then grounds, they would be almost entirely barren.

The Armenians are an honest, civil, polite people, scarce troubling themselves about any thing else but trade, which they carry on in most parts of the world, by which means they have fpread themselves over theeast, and also a great part of Europe; and wherever they come, commerce is carried on with spirit and ad-

The religion of the Armenians is the Christian, of the Eutychian feet: that is, they own but one nature in Jefus Christ; and when they speak of the hypostatical union, that he is perfect God and perfect man without mixture. They have a high effect for a book they call the Little Gofpel, which treats of the infancy of Jefus, and fays that the Virgin Mary being pregnant, her fifter Salome accused her of having profituted herfelf; to which the Virgin answered, that she needed only to lay her hand on her belly, and the would know how the came to be with child: this Salome accordingly did, and fire came out of her belly, which confumed the half of her arm; upon which she acknowledged her fault, and drew it back : after which it was healed by putting it to the fame place.

The Armenian clergy confift of patriarchs, archbishops, doctors, secular priests, and monks. The fecular pricits are not allowed to marry a fecond time: and therefore they take care to choose young healthy wives: they maintain themselves and families by following some occupation, insomuch that they have hardly time to perform their ecclefiaftical functions: they lie in the churches on the vigils of those days they are obliged to officiate.

The Armenian monks are of the order of St Bafil; and every Wednesday and Friday they cat neither fish, nor eggs, nor oil, nor any thing made of milk, and during Lent they live upon nothing but roots; they are allowed wine only on the Saturday in the Holy Week, and meat on the Easter Sunday. Besides the great Lent they have four others of eight days each, which are initituted to prepare for the four great feftiArmenus

Armenia vals of the Nativity, the Afcention, the Annunciation, and of St George; in which times they must not so much as speak of eggs, fish, oil, or butter.

The Armenians have feven facraments; baptifm, confirmation, penance, the eucharift, extreme unction, orders, and matrimony. In baptifm, the child is plunged three times into the water, and the fame form of words that is used with us is repeated every time; the priest then puts a finall cord made with filk and cotton on the neck of the infant, and anoints his forehead, chin, ftomach, arm pits, hands, and feet, making the fign of the crofs on each part. When the child is baptized, he is carried home by the godfather with the found of drums and trumpets. The women do not go to church' till forty days after their delivery; and they observe many Jewish customs.

At the communion, to which infants of two or three months old are admitted, the priests give a piece of the confectated hold foaked in the confectated wine. The elements are covered with a great veil, and placed in a cuphoard near the altar, on the fide of the gospels. When the priest takes the chalice and pattin, he is followed by his deacons and fubdeacons, with flambeaux and plates of copper furnished with bells: in this manner, with a cenfer before him, he goes in procession round the fanctuary; he then fets them on the altar, pronounces the words of confectation, and turns himfelf to the people, who fall down, kifs the earth, and beat their breafts: then, after taking it himself, he distributes the host soaked in wine to the people.

The Armenians feem to place the chief part of their religion in fallings and abitmences: and among the clergy, the higher the degree the lower they must live; infomuch that it is faid the archbishops live on nothing They confecrate holy water but once a-year; at which time every one fills a pot and carries it home, which brings in a confiderable revenue to the church.

ARMENIACA. See Prunus.

ARMENIAN, fomething belonging to or produced in Armenia: thus we fay, Armenian bole, Armenian flone, &c. See Bole, and Armenus Lapis.

ARMENTIERS, a small handsome town of the Netherlands, in the county of Flanders, and district of Ypres. It was taken by Lewis XIV. in 1667, who dismantled it; and it now belongs to the French. It is feated on the river Lis. E. Long. 3. 3. N. Lat.

50.40.

ARMENUS Lapis, Armenian stone, in natural hiftory, a mineral substance, which is but improperly called a flone; being no other than an ochreous earth, and properly called blue ochre. It is a very valuable fubstance in painting, being a bright and lively blue. It was in fo high effeem as a paint among the ancients, that counterfeits were continually attempted to ferve in its place. Theophrastus has recorded it as a thing judged worthy a place in the Egyptian annals, which of their Lings had the honour of inventing the factitious kind; and he tells us the genuine native substance was a thing of that value, that prefents were made of it to great persons, and that the Phænicians paid their tribute in it .- It is a very beautiful earth, of an even and regular texture; and of a fine blue, sometimes deeper, sometimes paler, and frequently mixed with green. It is foft, tender, and light; of an even, but somewhat dufty

furface: it adheres firmly to the tongue, and is dry, Amico but not harsh to the touch. It ensily breaks between the fingers, and does not stain the hands. It is of a Arminians. brackish disagreeable taste, and does not ferment with' acids. It is a very scarce fossil; but is found very pure, though but in small quantities, in the mires at Gosselaer in Saxony. It is frequently found spotted with green, and fometimes with black; and very often is mixed among the green ochre, called berggruen by the Germans, which has thence been erroneoully called by its name. See further the article BICE.

M

AMIERS, a town of Hainault, in the French Netherlands, feated on the river Sambre. E. Long. 3.45.

N. Lat. 50, 15.

ARMIGER, a title of dignity, belonging to such gentlemen as bear arms; and these are either by courtely, as fons of noblemen, eldeft fons of knights, &c.; or by creation, fuch as the king's fervants, &c. See

ARMILLARY, in a general fense, something

confilling of rings or circles.

Armillary Sphere, an artificial sphere composed of a number of circles of the mundane sphere, put together in their natural order, to ease and assist the imagination in conceiving the conflitution of the heavens, and the motions of the celestial bodies. The armillary sphere revolves upon its axis within a silvered horizon, which is divided into degrees, and moveable every way upon a brass supporter. The other parts are the equinoxial, zodiac, meridian, the two tropics, and the two polar circles. See Geography.

ARMILUSTRIUM in Roman antiquity, a feast held among the Romans, in which they facrificed, arm-

ed, to the found of trumpets.

ARMINIANS, a religious sect, or party, which arose in Holland, by a separation from the Calvinists. They followed the doctrine of Arminius (fee the next article); who, thinking the doctrine of Calvin, with regard to free-will, predefination, and grace, too fcvere, began to express his doubts concerning them in the year 1501; and upon further inquiry adopted fentiments more nearly refembling those of the Lutherans than of the Calvinists. After his appointment to the theological chair at Leyden, he thought it his duty to avow and vindicate the principles which he had embraced; and the freedom with which he published and defended them exposed him to the resentment of those that adhered to the theological fystem of Geneva, which then prevailed in Holland; but his principal opponent was Gomar, his colleague. The controversy which was thus begun, became more general after the death of Arminius, in the year 1609, and threatened to involve the United Provinces in civil discord. The Arminian tenets gained ground under the mild and favourable treatment of the magistrates of Holland, and were adopted by several persons of merit and distinction. The Calvinists, or Gomarists, as they were now called, appealed to a national fynod: accordingly the fynod of Dort was convened by order of the States General, in 1618, and was composed of ecclesiastical deputies from the United Provinces, as well as from the reformed churches of England, Hessia, Bremen, Switzerland, and the Palatinate. The principal advocate in favour of the Arminians was Episcopius, who, at that time, was professor of divinity at Leyden. It was first pro-

pofed

Againians posed to discuss the principal subjects in dispute, and that the Arminians should be allowed to state and vindicate the grounds on which their opinions were founded: but some difference arising as to the proper mode of conducting the debate, the Arminians were excluded from the assembly; their case was tried in their absence; and they were pronounced guilty of pestilential errors, and condemned as corrupters of the true religion. In consequence of this decision, they were treated with great feverity; they were deprived of all their posts and employments; their ministers were silenced, and their congregations were suppressed. However, after the death of Prince Maurice, who had been a violent partizan in favour of the Gomarists, in the year 1625, the Arminian exiles were restored to their former reputation and tranquillity; and under the to-

are very numerous.

The diftinguishing tenets of the Arminians may be comprised in the following five articles; relating to predestination, universal redemption, the corruption of

leration of the state, they crected churches and found-

ed a college at Amsterdam, appointing Episcopius to

be the first theological professor. The Arminian system has very much prevailed in England since the time of Archbishop Laud, and its votaries in other countries

man, conversion, and perseverance.

1. With respect to the first, they maintained, "That God, from all eternity, determined to bestow salvation on those who he foresaw would persevere unto the end in their faith in Christ Jesus; and to inslict everlasting pussishments on those who should continue in their unhelies, and resist usto the end his divine succours: so that election was conditional, and reprobation in like manner the result of foreseen insidelity and persevering wickedness."

2. On the fecond point the Arminian staught, "That Jesus Christ, by his sufferings and death, made an atonement for the fins of all mankind in general, and of every individual in particular; that, however, none but those who believe in him can be partakers of their divine benefit."

3. On the third article, they held, "That true faith cannot proceed from the exercise of our natural faculties and powers, nor from the force and operation of free will; since man, in consequence of his natural corruption, is incapable either of thinking or doing any good thing; and that therefore it is necessary, in order to his conversion and salvation, that he be regenerated and renewed by the operation of the Holy Ghost, which is the gift of God through Jesus Christ."

4. "That this divine grace, or energy of the Holy Ghoft, begins and perfects every thing that can be called good in man, and confequently all good works are to be attributed to God alone; that, neverthelefs, this grace is offered to all, and does not force men to act against their inclination, but may be resisted and rendered ineffectual by the perverse will of the impenitent sunner." Some modern Arminians interpret this and the last article with a greater latitude.

5. "That God gives to the truly faithful, who are regenerated by his grace, the means of preserving themselves in this state;" and though the first Armaians made some doubt with respect to the closing part of this article, their followers uniformly maintain, Vol. II. Part. I.

"that the regenerate may lose true justifying faith, Arminist forfeit their first of grace, and die in their fins."

The modern system of Arminianism likewise, sounded on a comprehensive plan projected by Arminius himfelf, as appears from a passage in his last will, extends the limits of the Christian church, and relaxes the bonds of fraternal communion in such a manner, that Chriflians of all fects and denominations, whatever their fentiments and opinions may be, Papists excepted, may be formed into one religious body, and live together in brotherly love and concord. But, in order to avoid the reproach of being altogether unconnected by any common principles, Episcopius drew up a confession of faith, expressed for the most part in words and phrases of Holy Scripture, which the Arminians have generally adopted, though not enjoined upon them by any authoritative obligation. The Arminians are also called Remonstrants, from an humble petition, entitled their Remonstrance, which, in the year 1610, they addressed to the States of Holland. Their principal writers are Arminius, Episcopius, Vorstius, Grotius, Curcellzus, Limborch, Le Clerc, and Wetslein; not to mention many others of more modern date.

ARMINIUS (James), whose real name in Low Dutch was James Harmanni, a famous Protestant divine, from whom the modern feet of Aiminians (fee the preceding article) take their name, was born at Oude-water, in Holland, in 1560. He was ordained minister at Amsterdam on the 11th of August 1588; where he foon diftinguished himself by his fermons, which were remarkable for their folidity and learning, and gained him univerfal applause: but Martin Lydias, professor of divinity at Francker, judging him a fit perfon to refute a writing in which Beza's doctrine of predellination had been attacked by fome ministers of Delft, Arminius at his entreaties undertook the talk : but upon thoroughly examining the reasons on both fides, he came into the opinions he proposed to destroy, and afterwards went still farther than the ministers of Delft had done. In 1600, he opposed those who maintained that ministers should subscribe the confession and catechism every year. In 1602, a pestilential disease raged at Amsterdam, during which he acted with the greatest resolution and courage, in assisting the poor, and comforting the fick; and Lucas Trelcatius and Francis Junius dying of that disease at Leyden, the curators of that university chose Arminus professor of divinity there, and he was afterwards made doctor of divinity. Disputes upon grace were soon after kindled in that university; and he was at length engaged in a new contest, occasioned by a disputation of his concerning the divinity of the Son. These contests, his continual labour, and the concern of feeing his reputation blafted by a multitude of flanders in relation to his opinions, impaired his health, and threw him into a fit of fickness, of which he died on the 19th of October 1609. Arminius was esteemed an excellent preacher: his voice was low, but very agreeable; and his pronunciation admirable: he was easy and affable to persons of all ranks, and facetious in his conversation amongst his friends. His great desire was, that Chriflians would bear with one another in all controverties which did not affect the fundamentals of their religion; and when they perfecuted each other for points of indifference.

curators of the university of Leyden had fo great a regard for him, that they fettled a pention upon his wife and children. He left several works, viz. 1. " Difputationes de diverfis Christianz religionis capitibus. 2. Orationes, Remque tractatus infigniores aliquot. 3. Examen modesti libelli Gulielmi Perkinsi de prædefinationis modo et ordine, itemque de amplitudine gratiz divinz. 4. Analysis capitis noni ad Romanos. 5. Dissertatio de vero et genuino sensu capitis septimi epikolæ ad Romanos. 6. Amica collatio cum D. Francisco Junio de prædestinatione per literas habita. 7. Epistola ad Hippolytum a collibus."

ARMIRO, a town of Macedonia, in European Turkey; feated on the gulf of Velo. E. Long. 23. 40.

N. Lat. 38. 34.

ARMISTICE, in military affairs, a temporary truce or cellation of arms for a very short space of time. The word is Latin, armistitium; and compounded of arm?, " arms," and flo " to fland, or ftop."

ARMOISIN, a filk stuff, or kind of taffety, manufactured in the East Indies, at Lyons, in France, and at Lucca in Italy. That of the Indies is slighter than those made in Europe.

ARMONIAC. Sec Ammoniac.

ARMONICA. See HARMONICA.

ARMORIAL, fomething relating to arms or coats of arms. Sec Arms and HERALDRY.

ARMORIC, or AREMORIC, fomething that belongs to the province of Bretagne, or Brittany, in France. The name Armorica was anciently given to all the northern and western coast of Gaul, from the Pyrenees to the Rhine; under which name it was known even in Cusar's time. The word is of Bas Breton origin, and denotes as much as maritime; compounded, according to M. Menage, of ar, "upon," and mure, "fea."

ARMORIST, a person skilled in the knowledge of armour.

ARMORUM concussio, the clashing of armour practifed by the Roman armies previous to an engagement, and intended to strike a panic into their enemies : It always followed the clafficum and the barritus. See CLASSICUM and BARRITUS.

ARMOUR a defensive habit, wherewith to cover and fecure the body from the attacks of an enemy. In ancient statutes this is frequently called barnefer-Parts of armour are, the buckler, cuirafs, helmet, coat

of mail, gauntlet, &c.

15 5

A complete armour anciently confilted of a calque or helm, a gorget, cuirais, gauntlets, tailes, brailets, cuishes, and covers for the legs, to which the spurs were fastened. This they called armour cap-a-pie; and was the wear of the cavaliers and men at arms.— The infantry had only part of it; viz. a pot or headpiece, a cuirals, and tailes; but all light. Laftly, The horfes themselves had their armour, wherewith to cover the head and neck .- Of all this furniture of war, scarce any thing is now retained except the cuirass; the gorget, or neck piece, worn by officers, being at present only a badge of honour, and of no defence.

The gallantry of going to the battle naked, without any describe armour, prevailed so far, that the French, during the reign of Louis XIV. were obliged to be continually issuing ordonnances to restrain it; in consequence of which the general officers, and those of the

Amount difference, it gave him the grand differiefaction. The cavalry, were obliged to refume the cuirafs, which yet Amount has been but ill observed.

Armour, Coat, is the eleutcheon of any person, or family, with its feveral charges, and other furniture; as mantling, creft, supporters, motto, &c .- Thus we fay, a gentleman of coat armour; meaning one who bears arms.

ARMOURER, a maker of arms, or armour.-The Roman armourers were disposed in certain places in the empire, it being forbid either to fell, or buy, or make arms elsewhere. They were exempt from all offices and taxes, and received a falary from the public.

When once they had taken the employment on themselves, neither they, nor their children, were allowed to quit it. To prevent this, they had a kind of note, or fligma, impressed on the arm, whereby they might be known. If any of them fled, or feereted their ware, the rest were obliged to answer for him; on account of which, the effects of fuch as died without a legal heir went to the college.-There were 15 armamentaries, or repositories of arms, in the Eastern empire, placed near the frontiers, and 19 in the Western.

Armourer of a ship, a person whose office is to take care that the arms be in a condition fit for service.

ARMOURY, a storehouse of arms, or a place wherein military habiliments are kept, to be ready for There are armouries in the Tower, and in all arfenals, citadels, castles, &cc.

Armoury is also used for a branch of heraldry; being the knowledge of coat armours, as to their bla-

zons, and various intendments.

ARMOZA, or HARMOZIA, a town in Caramania, at the mouth of the Anamis, which falls into the Perfian gulf (Arrian); Armuza, (Ptolemy); and from this the neighbouring island, and a small kingdom, take the modern name of Ormur, E. Long. 56. 17. N. Lat. 27. 20.

ARMS, ARMA, in a general fonce, includes all kinds of weapons, whether for defence or offence. Nicod derives the word from the Latin phrase quod operiant armos, because they cover the shoulders or sides; but Varro derives arma, ub arcendo, es quod arceant hostes. It is supposed that the first artificial arms were of wood, and were only employed against beasts; and that Belus, the fon of Nimrod, was the first that waged war: whence, according to some, came the appellation bellum. Diodorus Siculus takes Belus to be the same with Mars, who first trained soldiers up to battle .-Arms of stone, and even of brass, appear to have been used before they came to iron and Reel. Josephus affures us, that the patriarch Joseph first taught the use of iron arms in Egypt, arming the troops of Pharaoh with a calque and buckler.

What contributed most to render the Romans masters of the world, was, that having successively warred against all nations, they constantly renounced their own methods, arms, &c. whenever they met with better. Thus Romulus during his war with the Sabines, a bold and warlike nation, adopted their broad buckler in lieu of the small Argian buckler,

which he had used till that time.

The principal arms of the ancient Britons were hatchets, feythes, lances, fwords, and bucklers: the Saxons, &c. brought in the halbard, bow, arrows, arbalists, &c. By the ancient laws of England, every man Arms. was obliged to bear arms, except the judges and clergy. Under Henry VIII. it was expressly enjoined on all persons to be regularly instructed, even from their tender years, in the exercise of the arms then in use; viz. the long bow and arrows; and to be provided with a certain number of them. 33 Hen. VIII.

ARMS, Arma, in law, are extended to any thing which a man takes in his hand in his wrath, to cast

at, or strike another.

By the common law, it is an offence for persons to go or ride armed with dangerous weapons: but gentlemen may wear common armour, according to their quality, &c. 3d Inft. The king may prohibit force of arms, and punish offenders according to law; and herein every subject is bound to be aiding, Stat. 7. Edw. I. None shall come with force and arms before the king's justices, nor ride armed in affray of the peace, on pain to forfeit their armour, and to suffer imprisonment, &c. 2d Edw. III. c. 3, -

The importation of arms and ammunition are prohibited by 1 Jac. II. c. 8. and by 1 W. and M. stat. 2. c. 2. Protestant subjects may have arms for their defence. So likewise arms, &c. shipped after prohibition, are forfeited, by 29 Geo. I. c. 16. fec. 2.

Arms of offence in use among us at present are, the

fword, pistol, musket, bayonet, pike, &c.

The arms of the Highlanders are, the broad fword, target, poniard, and whinyar or durk, &c .- There are feveral acts of parliament for difarming the Highlanders; see 1 Geo. I. c. 54.; 11 Geo. I. c. 26.; 19 Geo. II. c. 39.; 21 Geo. II. c. 34.; 26 Geo. II. c. 22.

and 29.

Fire Arms are those charged with powder and ball : fuch are cannon, mortars, and other ordnance; mufkets, carabines, pittols, and even bombs, granadoes, carcasses, &c. In the History of the Royal Academy for the year 1707, we have an account of some experiments made with fire arms, differently loaded by M. Cassini. Among other things he observes, that by loading the piece with a ball which is fomewhat less than the calibre, and only laying a little gunpowder below the ball and a good deal above it, it will yield a vehement noise, but have no sensible effect or impulse on the ball .- This he takes to have been all the fecret of those people who pretended to fell the art of rendering one's felf invulnerable, or that proof.

Arms, pafe of, was a kind of combat in use among

the ancient cavaliers.

Arms, fland of. A stand of arms signifies a musket,

a bayonet, a fword, belt, and cartridge-box.

Arms of parade or courtefy, were those used in the ancient justs and tournaments; which were commonly unshod lances, swords without edge or point, wooden fwords, and even canes.

Arms denote the natural weapons, or parts of defence, of beafts: as claws, teeth, tulks of elephants, beaks of birds, &c.

ARMs, are also used figuratively for the profession of a foldier. Thus we say, He was bred to arms.

Arms, or armories, are also used in heraldry for marks of dignity and honour, regularly composed of certain figures and colours, given or authorized by fovereigns, and borne on banners, shields, coats, &c. for the distinction of persons, families, and states; and pasfing by descent to posterity.—They are called arms, in regard they are borne principally on the buckler. Arms cuirais, hanners, and other apparetus of way. They are also called coate of arms, comprermour, &c., because anciently embroidered on surcoats, &c. See HERALD-RY .- Some will have the name to have been first occalioned by the ancient knights, who in their justs and tournaments bore certain marks (which were frequently their mistress's favoura) in their armour, i. e. their helmets or suiclds, to distinguish them from each other.

ARMS at present follow the nature of titles, which being made hereditary, these are also become fo, being the feveral marks for diftinguishing of families and kindreds, as names are of persons and in-

dividuals.

ARMS are variously distinguished by the Heralds. Arms of alliance, are those which families or private persons join to their own, to denote the alliances which they have contracted by marriage.

Arms affumptive, are such as a man has a right to assume of himself, in virtue of some gallant action.

As, if a man who is no gentleman, of blood, nor has coat armour, takes a gentleman, lord, or prince, prifoner in any lawful war; he becomes entitled to bear the shield of such prisoner, and enjoy it to him and his heirs. The foundation hereof is that principle in military law, that the dominion of things taken in lawful war passes to the conqueror.

Arms, canting, are those wherein the figures bear an allusion to the name of the family .- Such are those of the family of La Tour in Auvergne, who bear a tower; that of the family of Prado in Spain, whose field is a meadow. Most authors hold these the most noble and regular, as is shown by an infinity of instances produced by Father Varrenne and Menetrier .-They are much debased when they come to partake of the Rebus.

Arms, charged, are such as retain their ancient integrity and value, with the addition of some new honourable charge or bearing, in confideration of some noble action.

Arms of community, are those of bishoprics, cities, univerlities, and other bodies corporate.

Arms of concession, or augmentation of honour, are either entire arms, or elfe one or more figures given by princes, as a reward for some extraordinary ser-

Arms of dominion, are those which emperors, kings, and fovereign states bear; being annexed to the terriritories which they possess. Thus the three lions are the arms of England; the fleurs de lys those of France,

Arms of family, or paternal arms, are such as belong to a particular family, and which no other per-

fon has a right to assume.

Arms, full, or entire, are such as retain their primitive purity, integrity, or value; without any alterations, diminutions, abatements, or the like.-It is a rule, that the simpler and less diversified the arms, the mere noble and ancient they are. For this reason Garcias Ximenes, first king of Navarre, and his successors for feveral ages, bore only gules, without any figure

The arms of princes of the blood, of all younger sons, and junior families, are not pure and full; but diftinguished and diminished by proper differences, &c.

Uu 2

Arms.

Arms of patronage, are those which governors of Agmirong provinces, lords of manors, &c. add to their family arms, in token of their peculiar superiority and juris-

> Arms of pretention, are those of fuch kingdoms or territories to which a prince or lord has some claim, and which he adds to his own, though the kingdoms er territories be possessed by a foreign prince or other lord. Thus the kings of England have quartered the arms of France with their own, ever fince the claim of Edward III. to that kingdom, in 1330.

> Arms of succession, are assumed by those who inherit ellates, manors, &c. by will, entail, or donation, and which they either impale or quarter with their own

ARMS are also said to be parted, couped, quartered, &c.

ARMS are faid to be false and irregular, when there is fomething in them contrary to the established rules of heraldry. As, when metal is put on metal, or colour on colour, &c.

The laws, and other affairs of arms, with the cognizance of offences committed therein, belong, among us, to the earl marshal and college of arms.

ARMS, in falconry, denote the legs of a hawk, from

the thigh to the foot. See FALCORY.

ARMSTRONG (Dr John), an eminent physician, poet, and miscellaneous writer, was born in Cattleton parish, Roxburghshire, where his father and brother were ministers; completed his education in the univerfity of Edinburgh, where he took his degree in physic, Feb. 4. 1732, with much reputation; and published his thesis, as the forms of that university require; the subject was De tabe purulenta. In 1735 he published a little humorous fugitive pamphlet in 8vo, entitled, " An effay for abridging the Study of Phyfic; to which is added a Dialogue betwixt Hygeia, Mercury, and Pluto, relating to the Practice of Phyfic, as it is managed by a certain illustrious Society. As also an Epittle from Usbek the Persian to Joshua Ward, Esq." This piece contains much fun and drollery; in the dialogue, he has caught the very spirit of Lucian. In 1737 he published a Synopsis of the History and Cure of the Venereal Disease, 8vo. This was foon followed by the Economy of Love; a poem which has much merit; but, it must be confesicd, is too ftrongly tinctured with the licentiouinels of Ovid. It is faid, however, that his maturer judgment expunged many of the luxuriances of youthful fancy, in an edition " revifed and corrected by the author" in 1768. It appears by one of the cases on literary property, that Mr Millar paid 50 guineas for the copyright of this poem, which was intended as a burlefque on some dictatic writers. It has been observed of Dr Armstrong, that his works have great inequalities, fome of them being possessed of every requisite to be lought after in the most perfect composition, while others can hardly be confidered as superior to the productions of mediocrity. The Art of preserving Health, his best performance, which was published in 1744, will transmit his name to posterity as one of the first English writers, has been honoured with the following

* Dr Mac- testimony of a respectable critic. On this work we tenzie's II.- thall also transcribe a beautiful eulogium from an emiflory of nent physician *: " Of all the poetical performances Pasith.

on this subject that have come to my hands, Dr Arm-Armstrong firong's Art of preserving Health is by far the best. To quote every charming description and beautiful Army. passage of this poem, one must transcribe the whole. We cannot, however, expect new rules, where the principal defign was to raife and warm the heart into a compliance with the folid precepts of the ancients, which he has enforced with great strength and elegance. And, upon the whole, he has convinced us, by his own example, that we ought not to blame antiquity for acknowledging

One power of physic, melody, and fong."

In 1746 Dr Armstrong was appointed one of the physicians to the Hospital for Lame and Sick Soldiers behind Buckingham house. In 1751 he published his poem on Benevolence, in folio; and in 1753, "Tafte, an Epille to a young Critic." In 1758 appeared, "Sketches or Essays on various subjects, by Launcelot Temple, Efq; in two parts." In this production, which possesses much humour and knowledge of the world, and which had a remarkably rapid fale, he is supposed to have been affifted by Mr Wilkes. In 1760 he had the honour of being appointed physician to the army in Germany, where in 1761 he wrote a poem called "Day, an Epille to John Wilkes of Aylesbury, Esq;" in this poem, which is not collected in his works, he wantonly hazarded a reflection on Churchill, which drew on him the serpent-toothed vengeance of that severest of satirifts, whose embalming or corrosive pen could deify or lampoon any man, according as he acquiefced with, or dissented from his political principles. In 1770 Dr Armstrong published a collection of "Miscellanies in 2 vols; containing, 1. The Art of preserving Health. 2. Of Benevolence, an Epistle to Eumenes. 3. Taite, an Epille to a young Critic, 1753. 4. Imitations of Shakespeare and Spenser. 5. The Universal Almanack, by Nouseddin Ali. 6. The Forced Marriage, a tragedy. 7. Sketches." In 1771 he published " A short Ramble through some parts of France and Italy, by Launcelot Temple;" and in 1773, in his own name, a quarto pumphlet, under the title of Medical Essays; towards the conclusion of which, he accounts for his not having such extensive practice as some of his brethren, from his not being qualified to employ the usual means, from a ticklish state of spirits, and a distempered excess of fensibility. He complains much of the behaviour of fome of his brethren, of the herd of critics, and particularly of the reviewers. He died in Sept. 1779; and to the no small surprise of his friends, left behind him more that 300l. faved out of a very moderate income, arising principally from his half-pay.

ARMUYDEN, a sea port town of the United Provinces, in the island of Walcherin, formerly very flourishing; but now inconfiderable, the sea having stopped up the harbour. The falt works are its chief resource.

E. Long. 3. 40. N. Lat. 51. 30.

ARMY, a large number of foldiers, confishing of horse and foot, completely armed, and provided with artillery, ammunition, provisions, &c. under the command of one general, having lieutenant-generals, major-generals, brigadiers, and other officers, under him. An army is composed of squadrons and battalions; and is usually divided into three corps, and formed into three lines: the first line is called the van-guard, the becoud the main-body, and the third the rear-guard or

Army. body of referve. The middle of each line is possessed by the foot; the cavalry form the right and left wing of each line; and fometimes they place squadrons of horse in the intervals between the battalions. When the army is drawn up in order of battle, the horse are placed at five feet distance from each other, and the foot at three. In each line the battalions are dillant from each other 180 feet, which is nearly equal to the extent of their front; and the same holds of the squadrons, which are about 300 feet distant, the extent of their own front. These intervals are left for the squadrons and battalions of the fecond line to range themselves against the intervals of the first, that both may more readily march through these spaces to the enemy: the first line is usually 300 feet distant from the second, and the second from the third, that there may be fufficient room to rally when the fquadrons and battalions are broken. See the article WAR.

This is to be understood of a land army only. A naval or sea army is a number of ships of war, equipped and manned with failors and marines, under the command of an admiral, with other inferior officers under him. See NAVAT. TACTICS.

It has been observed, that in Europe a prince with a million of subjects cannot keep an army of above 10,000 men, without ruining himself. It was otherwife in the ancient republics; the proportion of foldiers to the rest of the people, which is now as about 1 to 100, might then be as about 1 to 8. The reason feems owing to that equal partition of lands which the ancient founders of commonwealths made among their subjects; so that every man had a considerable property to defend; and means to defend it with: whereas, among us, the lands and riches of a nation being shared among a few, the rest have no way of subfishing but by trades, arts, and the like; and have neither any free property to defend, nor means to enable them to go to war in defence of it, without starving their families. A large part of our people are either artifans or fervants, and fo only minister to the luxury and effeminacy of the great. While the equality of lands subsisted, Rome, though only a little state, being refused the succours which the Latins were obliged to furnish after the taking of the city in the confulate of Camillus, prefently raised ten legions within its own walls; which was more, Livy affures us, than they were able to do in his time, though masters of the greatest part of the world. A full proof, adds the historian, that we are not grown stronger; and that what swells our city is only luxury, and the means and effects of it.

Our armies anciently were a fort of militia, composod chiefly of the vaffals and tenants of the lords. When each company had ferved the number of days or months enjoined by their tenure, or the customs of the fees they held, they returned home. The armies of the empire confift of divers bodies of troops furnished by the feveral circles. The gross of the French armies under the Merovingian race, confilled of infantry. Under Pepin and Charlemagne, the armies confifted almost equally of cavalry and foot: but since the declention of the Carlovingian line, the fees being become hereditary, the national armies, fays Le Gendre, are chiefly cavalry.

A well regulated standing army is greatly superior

to a militia; although a militia, it is to be observed, Army. after ferving two or three campaigns, may become equal to a standing army, and in every respect a match for veteran troops. See MILITIA.

One of the first standing armies of which we have a distinct account, in any well authenticated history, is that of Philip of Macedon. His frequent wars with the Thracians, Illyrians, Thessalians, and some of the Greek cities in the neighbourhood of Macedon, gradually formed his troops, which in the beginning were probably militia, to the exact discipline of a standing army. When he was at peace, which was very feldom, and never for any long time together, he was careful not to disband that army. It vanquished and subdued, after a long and violent struggle, indeed, the gallant and well exercised militias of the principal republics of ancient Greece; and afterwards, with very little ilruggle, the effeminate and ill exercifed militia of the great Persian empire. The fall of the Greek republics and of the Persian empire, was the effect of the irresissible fuperiority which a standing army has over every fort of militia. It is the first great revolution in the affairs of mankind of which history has preferred any distinct or circumstantial account.

The fall of Carthage, and the confequent elevation of Rome is the fecond. All the varieties in the fortune of those two famous republics may very well be accounted for from the same cause.

From the end of the first to the beginning of the fecond Carthaginian war, the armies of Carthage were continually in the field, and employed under three great generals, who fucceeded one another in the command; Hamilear, his fon-in-law Afdrubal, and his fon Hannibal; first in chastising their own rebellious slaves, afterwards in subduing the revolted nations of Africa; and, lastly, in conquering the great kingdom of Spain. The army which Hannibal led from Spain into Italy must necessarily, in those different wars, have been gradually formed to the exact discipline of a flanding army. The Romans, in the mean time, though they had not been altogether at peace, yet they had not during this period, been engaged in any war of very great confequence; and their military discipline, it is generally faid, was a good deal relaxed. The Roman armies which Hannibal encountered at Trebia, Thrafymenus, and Cannæ, were militia opposed to a standing army. This circumstance, it is probable, contributed more than any other to determine the fate of those battles.

The standing army which Hannibal left behind him in Spain, had the like fuperiority over the militia which the Romans fent to oppose it, and in a few years, under the command of his brother the younger Afdrubal, expelled them almost entirely from that country.

Hannibal was ill supplied from home. The Roman militia, being continually in the field, became in the progress of the war a well disciplined and well exercised standing army; and the superiority of Hannibal grew every day less and less. Addrubal judged it necessaryto lead the whole, or almost the whole, of the standing army which he commanded in Spain, to the affiltance of his brother in Italy. In this march he is faid to have been mifled by his guides; and in a country

temy. which he did not know, was furprised and attacked by another standing army, in every respect equal or superior to his own, and was entirely defeated.

When Afdrubal had left Spain, the great Scipio found nothing to oppose him but a militia inferior to his own. He conquered and subdued that militia; and in the course of the war, his own militia necessarily became a well disciplined and well exercised standing army. That standing army was afterwards carried to Africa, where it found nothing but a militia to oppose it. In order to defend Carthage, it became necessary to recal the flanding army of Hannibal. The difheartened and frequently defeated African militia joined it, and at the battle of Zama composed the greater part of the troops of Hannibal. The event of that day determined the fate of the two rival republics.

From the end of the fecond Carthaginian war till the fall of the Roman republic, the armies of Rome were in every respect standing armies. The standing aimy of Macedon made some resistance to their arms. In the height of their grandeur it cost them two great wars and three great battles, to fubdue that little kingdom; of which the conquest would probably have been fill more difficult, had it not been for the cowardice of its last king. The militias of all the civilized nations of the ancient world, of Greece, of Syria, and of Egypt, made but a feeble refishance to the standing armies of Rome. The militias of some barbarous nations defended themselves much better. The Scythian or Tartar militia, which Mithridates drew from the countries north of the Euxine and Caspian seas, were the most formidable enemies whom the Romans had to encounter after the fecond Carthaginian war. The Parthian and German militias too were always respectable, and upon feveral occasions gained very considerable advantages over the Roman armies. In general, however, and when the Roman armies were well commanded, they appear to have been very much superior.

Many different causes contributed to relax the difcipline of the Roman armies. Its extreme feverity was, perhaps, one of those causes. In the days of their grandeur, when no enemy appeared capable of oppofing them, their heavy armour was laid aside as unneceffarily burdenfome, their laborious exercifes were neglected as unnecessarily toilsome. Under the Roman emperors, befides, the flanding armies of Rome, those particularly which guarded the German and Pannonian frontiers, became dangerous to their masters, against whom they used frequently to set up their own generals. In order to render them less formidable, according to fome authors Dioclefian, according to others Constantine, first withdrew them from the frontiers, where they had always before been encamped in great bodies, generally of two or three legions each, and dispersed them in small bodies through the different provincial towns, from whence they were scarce ever removed, but when it became necessary to repel an invasion. Small bodies of foldiers quartered in trading and manufacturing towns, and feldom removed from those quarters, became themselves tradesmen, artificers, and manufacturers. The civil came to predominate over the military character; and the standing armies of Rome gradually degenerated into a corrupt, neglected, and undisciplined militia, incapable of relisting the attack of the German and Scythian militias, which foon

afterwards invaded the western empire. It was only Army. by hiring the militia of some of those nations to oppole to that of others, that the emperors were for some time able to defend themselves. The fall of the western empire is the third great revolution in the affairs of mankinds of which ancient history has preferved any diffinct or circumfrantial account. It was brought about by the irrefittible superiority which the militia of a barbarous has over that of a civilized nation; which the militia of a nation of shepherds has over that of a nation of husbandmen, artificers, and manufacturers. The victories which have been gained by militias have generally been not over flanding armies, but over other militias in exercise and discipline inferior to themselves. Such were the victories which the Greek militia gained over that of the Persian empire; and fuch too were those which in later times the Swifs militia gained over that of the Austrians and Burgun-

The military force of the German and Scythian nations, who established themselves upon the ruins of the western empire, continued for some time to be of the fame kind in their new fettlements as it had been in their original country. It was a militia of shepherds and husbandmen, which in time of war took the field under the command of the same chieftans whom it was accustomed to obey in peace. It was therefore tolerably well exercised and tolerably well disciplined. As arts and industry advanced, however, the authority of the chieftans gradually decayed, and the great body of the people had less time to spare for military exercises. Both the discipline and the exercise of the feudal militia, therefore, went gradually to ruin, and standing armies were gradually introduced to supply the place of it. When the expedient of a standing army, besides, had once been adopted by one civilized nation, it became necessary that all its neighbours should follow the example. They foon found that their fafety depended upon their doing fo, and that their own militia was altogether incapable of relifting the attack of fuch an army.

The foldiers of a standing army, though they may never have feen an enemy, yet have frequently appeared to possess all the courage of veteran troops, and the very moment that they took the field, to have been fit to face the hardiest and most experienced veterans. In a long peace the generals perhaps may fometimes forget their skill; but where a well regulated standing army has been kept up, the soldiers seem never to forget their valour.

When a civilized nation depends for its defence upon a militia, it is at all times exposed to be conquered by any barbarous nation which happens to be in its neighbourhood. The frequent conquests of all the civilized countries in Asia by the Tartars, sufficiently demonstrates the natural superiority which the militia of a barbarous has over that of a civilized nation. A well regulated standing army is superior to every militia. Such an army, as it can best be maintained by an opulent and civilized nation, so it can alone defend fuch a nation against the invalion of a poor and barbarous neighbour. It is only by means of a standing army, therefore, that the civilization of any country can be perpetuated, or even preserved for any considerable time.

As it is only by means of a well regulated standing army that a civilized country can be defended, to it is only by means of it that a barbarous country can be fuddenly and tolerably civilized. A standing army establishes, with an irresistible force, the law of the fovereign through the remotest provinces of the empire, and maintains some degree of regular government in countries which could not otherwise admit of any. Whoever examines with attention the improvements which Poter the Great introduced into the Ruffian empire, will find that they almost all resolve themselves into the establishment of a well regulated standing army. It is the instrument which executes and maintains all his other regulations. That degree of order and internal peace which that empire has ever fince enjoyed, is altogether owing to the influence of that army.

Men of republican principles have been jealous of a flanding army as dangerous to liberty. It certainly is fo, wherever the interest of the general and that of the principal officers are not necessarily connected with the support of the constitution of the state. The standing army of Cæfar deftroyed the Roman republic; the flauding army of Cromwell turned the long parliament out of doors. But where the fovereign is himself the general, and the principal nobility and gentry of the country the chief officers of the army; where the military force is placed under the command of those who have the greatest interest in the support of the civil authority, because they have themselves the greatest share of that authority; a standing army can never be dangerous to liberty: on the contrary it may, in fome cases, be savourable to liberty. The security which it gives to the fovereign renders unnecessary that troublefome jealoufy which in fome modern republics feems to watch over the minutest actions, and to be at all times ready to disturb the peace of every eitizen. Where the security of the magistrate, though supported by the principal people of the country, is endangered by every popular difcontent; where a fmall tumult is capable of bringing about in a few hours a great revolution; the whole authority of government must be employed to suppress and punish every murmur and complaint against it. To a sovereign, on the contrary, who feels hanfelf supported not only by the natural aristocracy of the country, but by a well regulated flanding army, the rudeft, the most groundless, and the most licentious remonstrances, can give little diffurbance. He can fafely pardon or neglect them, and his confciousness of his own superiority naturally disposes him to do so. That degree of liberty which approaches to licentiousness can be tolerated only in countries where the fovereign is secured by a well regulated standing army. It is in such countries only that the public fafety does not require that the fovereign should be trusted with any discretionary power for suppressing even the impertinent wantonness of this licentions liberty.

ARNALL (William), a noted political writer in defence of Sir Robert Walpole, was originally an attorney's clerk; but being recommended to Walpole, he employed him for a course of years in writing the Free Briton and other papers in defence of his administration. By the report of the secret committee, he appears to have received, in the space of four years, no

less than 10,997l. 6a. 8d. our of the treasury for his Armand writings t but spending his money as fall as it came, and his supplies stopping on Sir Robert's resignation, he died broken-hearted and in debt, in the 26th year of his age. His invention was so quiek, that his honourable employer used to say, no man in England could write a pamphlet in so little time as Arnall.

ARNAUD DE MEYEVEILH, or MEREUIL, a poet of Provence, who lived at the beginning of the 13th century. He wrote a book entitled Las recassens de sa contesse, and a collection of poems and sonnets. He died in the year 1220. Petrarch mentions him in his

Triumph of Love.

ARNAUD DE VILLA NOVA, a famous physician, who lived about the end of the 13th and beginning of the 14th century. He fludied at Paris and Montpelier, and travelled through Italy and Spain. He was well acquainted with languages, and particularly with the Greek, Hebrew, and Arabic. He was at great pains to gratify his ardent defire after knowledge; but this passion carried him rather too far in his researches: he endeavoured to discover future events by astrology, imagining this science to be infallible; and upon this foundation he published a prediction, that the world would come to an end in the middle of the 14th century. He practifed physic at Paris for some time; but having advanced fome new doctrines, he drew upon himfelf the refentment of the university; and his friends, fearing he might be arrefted, perfuaded him to retire from that city. Upon his leaving France, he retired to Sicily, where he was received by King Frederick of Arragon with the greatest marks of kindness and esteem. Some time afterwards, this prince fent him to France, to attend Pope Clement in an illness; and he was shipwrecked on the coult of Genoa, about the year 1313. The works of Aroaud, with his life prefixed, were printed in one volume in folio, at Lyons, in 1520; and at Dafil in 1585, with the notes of Nicholas Tolerus.

ARNAUD D'ANDILLY (Robert), the fon of a celebrated advocate of the parliament of Paris, was born in 1588; and being introduced young at court, was employed in many confiderable offices, all which he difcharged with great integrity and reputation. In 1644 he quitted bulinefs, and retraid into the convent of Port Royal des Champs, where he paffed the remainder of his days in a continued application to works of picty and devotion; and enriched the French language with many excellent translations of different writers, as well as with religious compositions of his own. He died in 1674, and his works are printed in 8 vols. folio.

ARNAUD (Anthony), brother of the preceding, and a doctor of the Sorbonne, was born in 1612. He published, in 1643, A treatife on frequent communion, which highly displeased the Jesuits; and the disputes upon grace, which broke out about this time in the university of Paris, and in which he took a zealous pair with the Jansenists, helped to increase the animosity between him and the Jesuits. But nothing raised so great a clamour against him as the two letters he wrote on Alfolution; in the second of which the faculty of divinity found two propositions which they tondemned, and M. Arnaud was expelled the society. Upon this he retired; and during a retreat which lasted near 25 years, he composed that great variety of works which are extant of his, on grammar, geometry, logic, ine-

taphyfice,

- 1

Arnheim.

Army taphysics, and theology. In 1679, he withdrew from France, living in oblcurity in the Netherlands, and died in 1694. His heart, at his own request, was fent to be deposited in the Port Royal. Arnaud had a remarkable firength of genius, memory, and command of his pen; nor did thefe decay even to the last year of his life. Mr Bayle fays, he had been told by persons who had been admitted into his familiar conversation, that he was a man very simple in his manners; and that unless any one proposed some question to him, or defired some information, he said nothing that was beyoud common conversation, or that might make one take him for a man of great abilities; but when he fet himself to give an answer to such as proposed a point of learning, he feemed as it were transformed into another man: he would then deliver a multitude of fine things with great perspicuity and learning, and had a particular talent at making himself intelligible to persons not of the greatest penetration.

ARNAY-LE-DUC, a town of France, in the duchy of Burgundy, which carries on a pretty good trade. It is feated on the Auxois, in a valley near the river Aroux. E. Long. 4. 26. N. Lat. 47. 7.

ARNDT (John), a famous Protestant divine of Germany, born at Ballenstad, in the duchy of Aphalt, in the year 1555. At first he applied himself to the study of physic: but falling into a dangerous sickness, he made a vow to change his profession for that of divinity, if he should be restored to health; which he accordingly did upon his recovery. He was minister first at Quedlinburg and then at Brunswick. He met with great opposition in this last city: his success as a preacher raifed the enmity of his brethren, who became his bitter enemies. In order to ruin his character, they ascribed a variety of errors to him; and persecuted him to fuch a degree, that he was obliged to leave Brunfwick, and retire to Isleb, where he was minister for three years. In 1611, George duke of Lunenburg, who had a high opinion of his integrity and fanctity, gave him the church of Zell, and appointed him fuperintendant of all the churches in the duchy of Lunenburg; which office he discharged for 11 years, and died in 1621. It is reported that he foretold his death. having said to his wife, upon his return home after his last fermon, that now he had preached his funeral fermon. He wrote in High Dutch A Treatife on true Christianity, which has been translated into several lan-

ARNE (Dr Thomas Augustine), distinguished by his skill in music, was the son of Mr Arne an upholsterer in Covent Garden, whom Addison is supposed to have characterized in N° 155 and N° 160 of The Tatler; and brother of Mrs Cibber the player. He was early devoted to music, and soon became eminent in his profession. July 6. 1759, he had the degree of doctor of music conferred on him at Oxford. His compositions are universally applauded, and he was also particularly skilful in instructing vocal performers. He died March 5. 1778, having written the following pieces: Artaxerxes, 1762; The Guardian outwitted,

1764; The Rose, 1778; all of them operas. ARNHEIM, a town of the Low Countries, in the

province of Guelderland, capital of Veluive. It is adorned with feveral fine churches, particularly that of

St Walburg and of St Euschius; which last has a very Arnica. high tower. The town has five gates, and feveral fine ramparts, part of which are washed by the Rhine, and the other parts have wide and deep ditches before them. There is a canal made between this place and Nimeguen, at the expence of both towns, on which boats pale backwards and forwards to carry on a trade between them. The air is very healthful; on which account it is inhabited by perfons of distinction.

E. Long. 5. 55. N. Lat. 52. O.
ARNICA, LEOPARDS BANE, in botany: A genus of the polygamia superflua order, belonging to the syngenefia class of plants; and in the natural method ranking under the 49th order, Composita-discoides. The receptacle is naked; the pappus is simple; and the filaments are five, without anthere. The

Species are feven, all natives of Ethiopia, except the two following: 1. The montana, with oval leaves, grows naturally on the Alps, and also upon many of the high mountains in Germany, and other cold parts of Europe. The roots of this species, when planted in a proper foil and fituation, spread very far under the furface, and put out many entire oval leaves, from between which the flower stems arise, which grow about a foot and a half high. The top is terminated by a fingle yellow flower, composed of many florets, like those of the dandelion. These are succeeded by oblong feeds, which are covered with down. 2. The scorpioides, with fawed leaves growing alternately, is a native of Bohemia and Siberia. The roots of this fort are much jointed, and divide into many irregular fleshy off-fets, which are variously contorted; from whence some superstitious persons have imagined that they would expel the poilon of scorpions, and cure the wounds made by the fling of that animal.

Culture. The first species delights in a moist shady fituation: it may be propagated by parting the roots in autumn when the stalks begin to decay; or by the feeds fown in autumn foon after they are ripe, for those fown in the spring often fail. The second fort is to be propagated in the fame manner. Both are very hardy, and require no other care than to be kept

free from weeds.

Medicinal Uses. The montana has an acrid bitter tafte, and when bruifed, emits a pungent odour, which excites fueezing. On this account the country people in some parts of Germany use it in snuff, and smoke it like tobacco. It was formerly represented as a remedy of great efficacy against effusions and suffusions of blood, from falls, bruiles, or the like; and it was then also mentioned as a remedy in jaundice, gout, nephritis, &c. but in these affections it is now very little, if at all, employed.

Of late it has been principally recommended in paralytic affections, and in cases where a loss or diminution of fense arises from an affection of the nerves, as in instances of amaurons. In these it has chiefly been employed under the form of infusion. From a drachm to half an ounce of the flowers has been directed to be infused in a pint of boiling water, and taken in different doles in the course of the day: sometimes it produces vomiting, fometimes fweating, fometimes diurefis; but frequently its use is attended with no fensible opention, unless it can be confidered as such, that in some

Arnifeus, cafes of paralyfis, the cure is faid to be preceded by a Arnobius peculiar prickling, and by shooting pains in the affects ~~ cd parts.

Befides being employed in paralytic affections, it has also been of late represented as a very powerful antispalmodic; and it is faid to have been successfully employed in fevers, particularly those of the interinitient kind, and likewise in cases of gangrene. In those difcales it has been faid to prove as efficacious as the Peruvian bark, when employed under the form of a pretty firong decoction taken in finall doles frequently repeated, or under the form of an electuary with honey.

But as these alleged virtues have not been confirmed by any trials made in Britain, its real influence still remains to be determined by future observations. It is, however, one of those active substances from which

fomething may be expected.

ARNISÆUS (Henningus), a philosopher and phyfician of great reputation, about the beginning of the 17th century. He was born at Halberstad in Germany, and was professor of physic in the university of Helmstad. His political works are much esteemed. The most remarkable of them is his book De authoritate principum in populum semper inviolabili, printed at Franciert in 1612. In this he maintains that the authority of princes ought not to be violated. He wrote allo upon the same doctrine his three books, De jure majestatis, printed at the same place in 1610; and his Reflectiones Politica, printed at Francfort in 1615. Having received an invitation to go to Denmark, he went thither, and was made counfellor and physician to the king. He travelled into France and England, and died in November 1635. Besides the pieces already mentioned, he wrote feveral philosophical, medicinal, and political treatifes.

ARNOBIUS, professor of thetoric at Sicca, in Numidia, towards the end of the third century. It was owing to certain dreams which he had that he became delirous of embracing Christianity. For this purpose he applied to the bishops to be admitted into the church. But they remembering the violence with which he had always opposed the true faith, had some distrust of him; and before they would admit him, infifted on some proofs of his fincerity. In compliance with this demand, he wrote against the Gentiles; wherein he has refuted the abfurdities of their religion, and ridiculed their false gods. In this treatise he has employed all the flowers of rhetoric, and displayed great learning: but from an impatience to be admitted into the body of the faithful, he is thought to have been in too great a hurry in composing his work, and thence it is that there does not appear in this piece such an exact order and disposition as could be wished; and not having a perfect and exact knowledge of the Christian faith, he published some very dangerous errors. Mr Bayle remarks, that his notions about the origin of the foul, and the cause of natural evil, and several other important points, are highly pernicious. St Jerome, in his epiftle to Paulinus, is of opinion that his Ayle is unequal and too diffuse, and that his book is written without any method; but Dr Cave thinks this judgment too severe, and that Arnobius wants neither elegance nor order in his composition. Vossius styles him the Varro of the ecclefiastical writers. Du Pin observes Vol. II. Part 1.

that his work's written in a mapper worthy of a pro- Accordfellor of "the toric: the turn of his fentiments is very oratorical; but his thyle is a little African, his expresfinal being harsh and inelegant. We have several editions of this work of Arnobius against the Gentiles, one published at Rome in 1542, at Bahl in 1546 and 1590, at Paris in 1570, at Antwerp in 1582, and one at Humburgh in 1610, with notes by Gebhard Elmeshorftius, befides many others. He wrote also a piece entitled De rhetorica influntione; but this is not ex-

ARNOLD, of Brescia, in Italy, diftinguished himfelf by being the founder of a feet which opposed the wealth and power of the Romish clergy. He went into France, where he fludied under the celebrated Peter Abelard. Upon his return to Italy, he put on the habit of a monk, and opened his invectives in the fireets of Brefels. The people crowded round him. He told them he was fent to reform abuses, to pull down the proud and to exalt the humble. He then poissed his declamation against the bishops, against the clergy, against the monks, and finally against the Roman poutiff himfelf: to the laity only he was indulgent. Churchmen, faid he, who hold benefices, bishops who have domains, and monks that have possessions, will all be damned. His hearers shouted approbation. These things, continued he, belong to the prince; he may give them to whom he pleases, but he must give them to the laity. It is on their tithes, and the voluntary contributions of the people, that those sons of God must live: they must be frugal, continent, and mor-

The church of Brescia was soon thrown into the greatest confusion, and the people, already prejudiced against their ministers, threatened to overturn their altars. The facred writings he urged in support of his affertions, and from them he denounced the vengcance of heaven against the violators of the law. Indeed, nothing could be more glaringly offensive than the oftentatious parade of the bishops and great abbots, and the foft and licentious lives of the monks and clergy.

In 1139 was celebrated a grand council at Rome. Arnold was cited to appear before it. His accusers were the bishop of Brescia, and many others, whom he had ridiculed and infulted. Nor from his judges could be look for much indulgence. He was found guilty, and fentenced to perpetual filence. Upon this he left Italy, croffed the Alps, and found a refuge in

Though Arnold had quitted Italy, yet had his opimons taken deep root, and Rome itself was infected by them. Irritated by the conduct of their master Innocent II. the Roman people affembled in the Capitol. It was proposed that the power of the pontiff, which they called exorbitant, should be restrained: this was carried: then suddenly, inspired as it were by the genius of the place, they moved that the fenate which for years had been abolished, should be re-Rored. The proposition was received with the loudest acclamations. Innocent in vain opposed the bold defign; there was a magic in it which spread irresishibly, and for a moment feemed to rouse the fallen spirit of the nation. The pope viewed with horror the reverse of fortune which threatened the tiara; to be shorn of maid his mighty power, and to become the mere shepherd of the Christian people, was a thought too afflicking: he fell fick and died.

Under his two immediate successors Celestin and Lucius, whose reigns were but of a few months, the Romans purfued their darling object. They waited on the latter, and, in an imperious tone, demanded the reflitution of all the honours and civil rights which had been usurped from the people. The prince of the fenate, faid they, whom we have chosen, will belt administer the important trust : the tithes and offerings of the faithful will fufficiently answer all the exigencies of your holiness: It was thus that our ancient bishops lived .- Lucius survived this event but a few days. His fuccessor was Eugenius III. the friend and disciple of the renowned Bernard. The night before his confecration the senators assembled, and it was agreed, that either he should solemnly confirm all their proceedings, or they would annul his election. This resolution was notified to him. He called together his friends; and it was their advice, that he should neither accede to the extravagant demand, nor expose himself, by a refufal, to the fury of the populace. He therefore silently withdrew from Rome, and retired to a neighbouring fortress. Here the ceremony of his consecra-

tion was performed.

Arnold, who in banishment had contemplated the effect of his admonitions on the minds of the Romans. and the fuccels which feemed to follow their exertions, was now informed that the pope had retired, and that the gates of the capital were open to receive him: it was likewise suggested to him, that his presence was more than ever necessary, to give energy to their refolves, form to their plans, and stability to their undertakings. Arnold took fire at the news; an unufual swell of enthusiasm filled his breast; and he fancied that, like Junius Brutus, he was called at once to give liberty to Rome. At his appearance a new stream of vigour animated the citizens; they called him their friend and deliverer. The Brescian walked amongst them; his deportment was humble, his countenance emaciated, his address affable, and he spoke to them of moderation, of submission, of obedience. With the nobles and new fenators he held another language; though to them also he was mild and diffident, speaking much of virtue and of respect for religion and the laws. But no fooner was he fenfible of his own real influence, and faw the lengths to which the revolters had already carried their defigns, than he threw afide the mask, and appeared in his own character, daring, impetuous, self-sufficient, vain. He harangued the people; he talked of their forefathers the ancient Romans, who, by the wildom of their fenate and the valour of their armies, had conquered nations and subdued the earth. He dwelt on the names and the a. chievements of the Bruti, the Gracchi, and the Scipiost and of these men, said he, are you not the children? He advised, that the capitol be instantly repaired; that the equestrian order be restored; that the people have their tribunes; that dignity attend the senate; and that the laws, which had been filent and neglected, be revived in all their vigour. He spoke of the pope as of a deposed and banished tyrant: " But should you again be disposed (continued he) to admit him within these walls; first fix your own rights and determine

his. He is but your bishop: let him therefore have Arnold. his spiritual jurisdiction. The government of Rome, its civil establishments, and its territories, belong to you. These you will keep if you have the spirit of men and the hearts of Romans." Fired by this harangue, the people, headed by the most disaffected of the nobles, publicly attacked the few cardinals and churchmen who remained in the city; they fet fire to the palaces; and they compelled the citizens to fwear obedience to the new government. Moderate men, who saw the folly of the attempt, were shocked at these excesses of popular phrenzy; but it was in vain to oppose the torrent: they submitted, looking forward with some curiosity to the termination of an event which had begun in extravagance, and must end in

disappointment.

Eugenius till now had viewed, with some concern, the wild derangement of his people: but when it scemed that their eyes opened to their own excesses, he could be inactive no longer. He excommunicated the ringleaders of the faction; and at the head of his troops, who were chiefly composed of Tibuttini, a people always hostile to the Romans, he marched against the enemy. His friends within the walls, who were numerous, co-operated with his defigns, and in a few days overtures for peace were made to the pontiff. He acceded to them, but on condition that theyshould annul the arrangements they had made, and if they would have fenators, that they should acknowledge all their power was from him. The people were fatisfied, and they threw open the gates, through which Eugenius entered, amid the acclamations of a fawning and inconstant multitude .- Before this event Arnold had retired; but he left behind him many friends strongly attached to his person and principles. Of himfelf we hear little more till the reign of Adrian our countryman; when, on account of fresh tumults, he and his adherents were excommunicated, and Rome was threatened with an interdict unless they expelled the whole party from their walls. This they did. The Arnoldifts retired with their champion into Tuscany, where he was received as a prophet and honoured as a faint. His enemies, however, prevailed; he was made prisoner, and conducted under a strong escort to Rome. In vain was great interest made to save his life; he was condemned and executed, and his ashes thrown into the Tiber, lest the people should collect his remains and venerate them as the relicks of a fainted martyr.

" Such was Arnold of Brescia; a man (says Mr Berington *), whose character, whose principles, and . Hist. of whose views, we perhaps should be disposed to admire, the Lives of had his life been recorded by unprejudiced historians, Abelard and and not brought down to us drawn in the blackest co- Helosfa. lours which party, bigotted zeal, and enthusiasm, could lay on. He was rash, misjudging, and intemperate, or never would he have engaged in fo unequal a contest.-The view of such a phenomenon in the 12th century excites a pleasing admiration. To attack the Roman pontiff and his clergy in the very centre of their powery required a more than common share of fortitude; to adopt a fettled scheme of restoring to its pristine glory the republic of Rome, demanded a firetch of thought comprehensive and enterprising ; and to forego the ease and indulgence of a diffipated age, for the reformation of manners and the suppres-

According fion of what he thought usurped dominion, argued a character of mind difinterested, generous, and benevo-Arnulph. lent. But Arnold, like other reformers, went too far; and passion foon viriated undertakings which were begun perhaps with motives the most laudable.-The readiness with which the Roman people embraced this plan of lowering the jurisdiction of the pontiff, and refraining it within those bounds which the true spirit of Christianity had fixed, at once shows that they could reason justly, and that they considered the unbounded fway of the triple crown, to which reluctantly they fubmitted, as an assumed prerogative, to which violence or misconstruction, and not Christian right, had given efficacy."

ARNOLDISTS, in church history, a feet to called from their leader Arnold of Brescia. See the preced-

ing article.

ARNOLDUS (Gothofredus), pastor and inspector of the churches of Perleberg, and historiographer to the king of Pruffia, was born at Annaburg in the mountains of Misnia in 1666. He was a zealous defender of the Pietifts, a fect among the German Protestants, and composed a great number of religious works; particularly an Ecclefiaflical Hiftory, which exposed him to the refentment of the divines; and another giving an account of the doctrines and manners from the first ages, in which he frequently animadverts upon Cave's Primitive Christianity. He died in 1714. Various are the opinions concerning Arnoldus in Germany; fome of his own countrymen and profession extolling him to the skies as a saint of the last century, and setting an inestimable value upon his works; while others pronounce damnation upon him as an arch-heretic, and condemn his writings as heterodox.

ARNON (anc. geog.), a brook running between the horders of the Moabites and Ammonites on the other fide Jordan (Moses, Joshua): Josephus calls it a river rifing on the borders of Arabia, and at length falling into the Dead sea. It is also called the river of Gad, as appears 2 Sam. xxv. 5. compared with 2 Kings x.

ARNOT, in botany, the English name of the bunium. See Buntum.

ARNOTTO. The same with Anotta. See Anot-TA and BIXA.

ARNSTADE, a town of Germany, in Thuringia, on the river Gera. E. Long. 11. 3. N. Lat. 50. 54.

ARNULPH, or ERNULPH, bishop of Rochester in the reign of Henry I. He was born in France, where he was forne time a monk of St Lucian de Beauvais. The monks led most irregular lives in this monastery; for which reason he resolved to quit it, but first took the advice of Lanfranc archbishop of Canterbury, under whom he had studied in the abbey of Becc, when Lanfranc was prior of that monastery. This prelate invited him over to England, and placed him in the monastery of Canterbury, where he lived a private monk till Lanfranc's death. When Anselm came to the archiepiscopal fee, Arnulph was made prior of the monastery of Curterbury, and afterwards abbot of Peterborough. In 1115, he was confecrated bishop of Rochefter, which fee he held nine years, and died in March 1124, aged 84

Arnulph write, 1. A piece in Latin concerning the foundation, endowment, charters, laws, and other things

relating to the church of Rochester : it is generally known by the title of Tietus Roffens, and is preferred in the archives of the cathedral charch of Rocheller. 2. An Epifile in Answer to Tome Quellious of Lambert abbot of Munfter; and, J. An Epifile on inceffuous Marriage.

ARNUS, now Arno, a very rapid river of Tulcany, which it divides, and in its course washes Florence and Pila; rifing in the Apennines, to the east of Florence, near a village called S. Maria della Gratie, on the borders of Romagna, 15 miles to the west of the sources of the Tiber; and then turning fouthwards toward; Arretium, it is there increased by the lakes of the Clanis; after which it runs westward, dividing Florence into two parts, and at length washing Pifa, falls eight

miles below it into the Tuscan sea.

ARNWAY (John), a clergyman diffinguished by his benevolence and loyalty to King Charles I. was descended from a very good family in the county of Saz lop, from which he inherited a confiderable effate. He was educated at Oxford; and, having received hely orders, obtained the rectories of Hodnet and Ightfield, where he diftinguished himself by his piety and exemplary charity: for it was his custom to clothe annually 12 poor people, and every Sunday to entertain as many at his table, not only plentifully, but with intimacy and respect. The civil war breaking out, he preached against rebellion, and raised and clothed eight troopers for the fervice of King Charles I. upon which his house was plundered by the parliament's army. He then went to Oxford to serve the king in person, which subjected him to a new train of misfortunes: for his estate was foon after fequeftered, and himfelf imprisoned till the king's death; after which he went to the Hague, where he published, 1. The Tablet, or the Moderation of Charles I. the Martyr; and, 2. An Alarm to the Subjects of England. He at last went to Virginia, where he died in 1653.

AROBE. See ARROBAS.

AROLEO, an American weight, equal to 25 of

AROMA PHILOSOPHORUM, denotes either faffron, or the aroph of Paracelfus; as aroma germanicum, de-

notes elecampane. See AROPH.

AROMATA (anc. geog.), a town of Lydia, famous for its generous wines; and hence the appellation, (Strabo.) Also the name of a trading town, and promontory of Ethiopia, at the termination of the Sinus Avalites of the Red fea, (Arrian).

AROMATIC, an appellation given to fuch plants as yield a brifk fragrant smell, and a warm taste; as all kinds of spices, &c. See Materia Medica.

ARONA, a town of Italy, in the duchy of Milan, with a strong castle. It stands on the lake Maggiore.

E. Long. 8. 25. N. Lat. 45. 41,

ARONCHES, a town of Portugal, in Alentejo, on the confines of Spain, feated on the river Caro. It is well fortified, and has about 500 inhabitants. W. Long. 5. 16. N. Lat. 14. 39.

AROOL, a town of the empire of Russia, in the Ukrain, scated on the river Occa. E. Long. 38. 15. N. Lat. 51. 48.

AROPH, a contraction of aroma philosophorum; a name given to faffron.

AROPH Paracelfi, a name given to a kind of chemi-X x 2

Aroph.

cal flowers, probably of the fame nature with the Ens Voscria, elegantly prepared by sublimation from equal quantities of lagis associates and fall ammoniac.

Anonh is also combiled frequently by Paracellus

in a lende lyndayed out with liebouwiphic.

AROSBAY, a town of the East Indies, on the coast of the island of Madura, near Java. E. Long. 14. 30. N. Lat. 9. 30.

AROURA, a Grecian measure of to feet. It was more frequently used for a iquare measure of half the plethron. The Egyptian aroura was the square of 100

ARPAD (anc. geog.), is thought to have been a city of Syria. It was always placed with Hamath, (2 Kings aviii. 34. xix. 13. Isaiah x. 9. xxxvi. 19. xxxvii. 13. Jerem. xlix. 23.) Sennachorib boatts of having reduced Arpad and Hamath, or of having destroyed the gods of these two places. Hamath is known to be the fame with Emefa; and it is thought that Arpad is the same with Arad or Arvad, as it is fometimes called in Hebrew. See ARAD.

ARPAGIUS, or HARPAGIUS among the ancients, a person who died in the cradle, at least in early youth. The word is formed from the Greek newalw, I fnatch. The Romans made no funerals for their arpagis. They neither burnt their bodies, nor made tombs, monuments, or epitaphs for them; which occasioned Juvemal to fay,

—Terra clauditur infans Et minor igne rogi.

In after times it became the custom to burn such as had lived to the age of 40 days, and had cut any teeth; and thefe they called Agrantos, or Agranguesos, q. d. rapti, ravished. The usage seems to have been borrowed from the Greeks; among whom, Euflathius affures us, it was the cultom never to bury their children either by night or full day, but at the first appearance of the morning; and that they did not call their departure by the name of death, but by a fofter appellation, Husgas neways, importing that they were ravished by Aurora, or taken away to her embraces.

ARPENT, figuifies an acre or furlong of ground; and according to the old French account in Doomfdaybook, 100 perches make an arpent. The most ordinary acre, called l'arpent de France, is 100 perches fquare: but some account it but half an acre.

ARPHAXAD, the fon of Shem and father of Salah. Arphaxad was born in the year of the world 1658, a year after the deluge, and died in the year of the world 2006, at the age of 438 years, (Gen. xi. 12, &c.)

ARPI. Sec Argos Hippium.

1.4

ARPINAS, or Anpino, (Joseph Calar), a famous painter, born in the year 1560, at the caltle of Arpinas, in the kingdom of Naples. He lived in great intimacy with Pope Clement VIII. who conferred upon him the honour of knighthood, and bestowed on him many other marks of his friendship. In the year 1600, he went to Paris with Cardinal Aldobrandin, who was fent legate to the French court on the marriage of Henry IV. with Mary of Medicis. His Christian majefty gave Arpinus many confiderable presents, and created him a knight of St Michael. The colouring of this painter is thought to be cold and inanimate; yet

there is spirit in his designs, and his compositions have Arpinum fomowhat of fire and elevation. The touches of his pencil being free and bold, give therefore pleafure to Arraigncommeisseurs in painting; but they are generally incorrect. What he painted of the Roman history is the most escemed of all his works. The French king has in his collection the following pieces of this mafter, viz. the Nativity of our Saviour, Dirna and Acteon, the Rape of Europa, and a Sulanna. He died at Rome in 1640.

ARPINUM, a town of the Volsci, a little to the east of the confinence of the rivers Liris and Fibreaus, in the Terra di Lavora; now decayed, and called Arpino. It was the native place of Cicero, and of C.

Marius, (Sallust:)
ARQUA, a town of Italy, in the Paduan, and territory of Venice, remarkable for the tomb of Petraich. E. Long. 11. 43. N. Lat. 45. 43.

ARQUEBUS. See HARQUEBUS.

ARQUES, a town of Normandy, in France, scated on a small river of the same name. E. Long. 1. 30. N. Lat. 49. 5

ARRÁCHEE, in heraldry, a term applied to the representations of plants torn up by the roots.

ARRACHIS, in botany. See ARACHIS.

ARRACK. See ARACK.

ARRAGON, a province of Spain, bounded on the north by the Pyreneau mountains, which separate it from France; on the west by Navarie and the two Castiles; on the fouth, by Valencia; and on the eatl, by Catalonia. It is in length about 18c miles, and in breadth 149; but the land is mountainous, dry, fandy or flony, badly cultivated, and worfe peopled. However it does not want rivers; for besides the Ebro. which croffes it in the middle, there are the Xalo, the Cinea, the Galego, and the Arragon. The air is pure and wholesome; and there are mines of iron, and some fay of gold. The most fertile parts are about the rivers: for there the land produces corn, wine, oil, flax, hemp, various fruits, and a small quantity of sasfron, befides large flocks of theep, and plenty of game in the woods.

The Arragonese have the character of being bold, courageous, and well bred; but positive in their opinions, and bigotted in their religion. These were the first of the Spaniards that threw off the Moorish yoke. Saragoffa is the capital of this province; and the other chief towns are Balbastro, Jaca, Sarazona, Haesca, Calatajud, Albarrazin, Trevel, Daroca, and Boria.

ARRAIGNMENT, in law, the arraigning or fetting a thing in order, as a person is said to arraign a writ of novel diffcifin, who prepares and fits it for

ARRAIGNMENT is most properly used to call a person to answer in form of law upon an indictment, &c.

When brought to the bar, the criminal is called upon by name to hold up his hand; which though it may feem a triffing circumstance, yet is of this importance, that by the holding up of his hand conflat de persona, and he owns himself to be of that name by which he is called. However it is not an indispensible ceremony; for being calculated merely for the purpole of identifying the person, any otheracknowledgement will answer the purpose as well : therefore, if the prisoner obitinately and contemptuously refuses to hold

Arraign- up his hand, but confesses he is the person named, it is fully fufficient.

> Then the indictment is to be read to him diffinctly in the English tongue (which was law, even while all other proceedings were in Latin), that he may fully understand his charge. After which it is to be demanded of him, whether he be guilty of the crime whereof he stands indicted, or not guilty?

> When a criminal is arraigned he either flands mute, or confesses the fact, or else he pleads to the indictment.

> 1. If he fays nothing, the court ought ex officio to impannel a jury to inquire whether he stands obstinately mute, or whether he be dumb en visitatione Dei. the latter appears to be the case, the judges of the court (who are to be of counfel for the priloner, and to fee that he hath law and justice) shall proceed to the trial, and examine all points as if he had pleaded not guilty. But whether judgment of death can be given against such a prisoner, who hath never pleaded, and can fay nothing in arrest of judgment, is a point yet undetermined.

> If he be found to be obstinately mute (which a prifoner hath been held to be that hath cut his own tongue), then, if it be on an indictment of high treafon, it hath long been clearly fettled, that standing mute is equivalent to a conviction, and he shall receive

the same judgment and execution.

The English judgment of penance for standing mute was as follows: That the prifoner be remanded to the prison from whence he came, and put into a low dark chamber; and there be laid on his back, on the bare floor, naked, unless where decency forbids; that there be placed upon his body as great a weight of iron as he could bear, and more; that he have no fuftenance, fave only, on the first day, three morfels of the worst bread; and, on the second day, three draughts of standing water that should be nearest to the prison door; and in this fituation this should be alternately his daily diet, till be died, or, as anciently the judgment ran, till be an frwered.

It hath been doubted whether this punishment subfifted at the common law, or was introduced in confequeuce of the statute Westin, I. 3 Edw. I. c. 12. which feems to be the better opinion. For not a word of it is mentioned in Glauvil or Bracton, or in any ancient author, case, or record (that hath yet been produced), previous to the reign of Edward I.: but there are instances on record in the reign of Henry III. where persons accused of felony, and standing mute, were tried in a particular manner, by two fuccessive juries, and convicted: and it is afferted by the judges in 8 Henry IV. that, by the common law before the statute, standing mute on an appeal amounted to a conviction of the felony. This statute of Edward I. directs fuch persons, " as will not put themselves upon inquests of felonies before the judges at the suit of the king, to be put into hard and strong prison (foients mys en la prisone fort et dure) as those which refuse to be at the common law of the land." And, immediately after this statute, the form of the judgment appears in Flea and Britton to have been only a very strait confinement in prison, with hardly any degree of fustenance; but no weight is directed to be laid upon the body, fo us to haften the death of the miferable

fufferer; and indeed any furcharge of punishment on Arraiga persons adjudged to penance, so as to shorten their ment, lives, is reckoned by Horne in the Mirror as a species of criminal homicide. It also clearly appears, by a record of 31 Edw. III. that the prisoner might then possibly subast for 40 days under this lingering punishment. It is therefore imagined that the practice of loading him with weights, or, as it is usually called, preffing bim to death, was gradually introduced between 31 Edward III. and 8 Henry IV. at which last period it first appears upon the books; being intended as a species of mercy to the delinquent, by delivering him the fooner from his torment: and hence it is also probable, that the duration of the penance was then first altered; and instead of continuing till be answered, it was directly to continue till be died, which must very foon happen under an enormous pressure. .

The uncertainty of its original, the doubts that were conceived of its legality, and the repugnance of its theory (for it rarely was carried into practice) to the humanity of the laws of England, all concurred to require a legislative abolition of this cruel process, and a reflitution of the ancient common law; whereby the flanding mute in felony, as well as in treason and in trespass, amounted to a confession of the charge.

2. If the prisoner made a simple and plain confession, the court hath nothing to do but to award judgment : but it is usually very backward in receiving and recording such confession, out of tenderness to the life of the subject; and will generally advise the prisoner to retract it, and,

3. Plead to the indictment; as to which, fee the ar-

ticle PLEA of Indiament.

ARRAN, an island of Scotland, in the frith of Clyde, between Kintyre and Cunningham. Of this island the best description we have is that given by Mr Pennant in his Tour through Scotland, Vol. II. 172-

"Arran, or properly Arr-inn, or, ' the island of mountains,' feems not to have been noticed by the ancients, notwithstanding it must have been known to the Romans, whose navy, from the time of Agricola, had its station in the Glotte Effuarium, or the Frith of Clyde. Camden, indeed, makes this island the Glotta of Antonine, but no fuch name occurs in his Itinerary: it therefore was bellowed on Arran by some of his commentators. By the immense cairns, the vast monumental stones, and many relicks of Druidism, this island must have been confiderable in very ancient times. Here are still traditions of the hero Fingal, or Fin Mac Coul, who is supposed here to have enjoyed the pleasures of the chase; and many places retain his name: but I can discovernothing but oral history that relates to the island till the time of Magnus the Barefooted, the Norwegian victor, who probably included Arran in his conquells of Kintyre. If he did not conquer that illand, it was certainly included among those that Donald Bane was to cede; for it appears that Acho, one of the succesfors of Magnus, in 1263, laid claim to Arran, Bute, and the Cumrays, in confequence of that promife: the two first he subdued, but the defeat he met with at Largs foon obliged him to give up his conquells. Arran was the property of the crown. Robert Bruce retired thither during his diffresses, and met with protection from his faithful vallals. Numbers of them fol-

350 lowed his fortunes; and after the battle of Bannockburn he rewarded feveral, fuch as the Mac-cooks, Mackinnous, Mac-brides, and Mac-louis, or Fullertons. with different charters of lands in their native country. All these are now absorbed by this great family, except the Fullertons, and a Stewart, defeended from a son of Robert III. who gave him a settlement here. In the time of the Dean of the Isles, his descendant possessed Castle Douan; and be and his bluid, says the Dean, are the best men in that countrey. About the year 1334, this island appears to have formed part of the estate of Robert Stewart, great steward of Scot-land, afterwards Robert II. At that time they took arms to support the cause of their master; who afterwards, in reward, not only granted at their request an immunity from their annual tribute of corn, but added feveral new privileges, and a donative to all the inhabitants that were present. In 1456, the whole island was ravaged by Donald carl of Ross and lord of the Isles. At that period, it was still the property of James II.; but in the reign of his fuccessor James III. when that monarch matched his fifter to Thomas lord Boyd, he created him earl of Arran, and gave him the island as a portion. Soon after on the difgrace of that family, he caused the counters to be divorced from her unfortunate husband; and bestowed both the lady and island on Sir James Hamilton, in whose family it continues to this time, a very few farms excepted.

"Arran is of great extent, being 23 miles from Sgreadan Point north to Beinnean fouth; and the number of inhabitants are about 7000, who chiefly inhabit the coasts; the far greater part of the country being uninhabited by reason of the vast and barren mountains. Here are only two parishes, Kilbride and Killmore; with a fort of chapel of ease to each, founded in the last century, in the golden age of this island, when it was bleffed with Anne duchels of Hamilton. whose amiable disposition and humane attention to the welfare of Arran render at this distant time her memory dear to every inhabitant. The principal mountains of Arran are, Goatfield, or Gaoilbheinn, or "the mountain of the winds," of a height equal to most of the Scottish Alps, composed of immense piles of moorstone, in form of wool packs, clothed only with lichens and mosses, inhabited by eagles and ptarmigans; Bein-bharrain, or "the sharp pointed;" Ceum-na-caillich, "the step of the carline or old hag;" and Grianan-Athol, that yields to none in ruggedness. The lakes are, Loch-jorfa, where falmon come to spawn; Lochtana; Loch-nah-jura, on the top of a high hill; Lochmhachrai; and Loch-knoc-a-charbeil, full of large cels. The chief rivers are, Abhan-mhor, Moina-mhor, Slondrai-machrei, and Jorfa; the two last remarkable for the abundance of falmon.

"The quadrupeds are very few; only otters, wild cats, shrew mice, rabbits, and bats: the slags, which used to abound, are now reduced to about a dozen. The birds are, eagles, hooded crows, wild pigeons, stares, black game, grous, ptarmigans, daws, green plovers, and curlews. It may be remarked, that the partridge at present inhabits this island, a proof of the advancement of agriculture.

"The climate is very fevere: for befides the violence of wind, the cold is very rigorous; and fnow lay here in the valleys for 13 weeks of the last winter. In summer, the air is remarkably falubrious; and many in- Arran. valids refort here on that account, and to drink the whey of goats milk.

"The principal difease here is the pleurify: smallpox, mealles, and chincough, visit the island once in feven or eight years. The practice of bleeding twice every year feems to have been intended as a preventive against the pleurify: but it is now performed with the utmost regularity at spring and fall. The duke of Hamilton keeps a furgeon in pay; who at those sea-fons makes a tour of the island. On notice of his approach, the inhabitants of each farm affemble in the open air; extend their arms; and are bled into a hole made in the ground, the common receptacle of the vital fluid. In burning fevers, a tea of wood furrel is used with success, to allay the heat. An insusion of ramfons, or allium urfinum, in brandy, is effected here a good remedy for the gravel.

"The men are strong, tall, and well made; all speak the Erfe language, but the ancient habit is entirely laid afide. Their diet is chiefly potatoes and meal; and during winter, some dried mutton or goat is added to their hard faic. A deep dejection appears in general through the countenances of all: no time can be spaced for amusement of any kind; the whole being given for procuring the means of paying their rent, of laying in their fuel, or getting a feanty pittance of meat

and clothing.

"The leafes of farms are 19 years. The fucceeding tenants generally find the ground little better than a caput mortuum: and for this reason: Should they at the expiration of the leafe leave the lands in a good flate, tome avaricious neighbours would have the preference in the next fetting, by offering a price more than the person who had expended part of his substance in enriching the farm could peffibly do. This induces them to leave it in the original flate. The method of fetting a farm is very fingular; each is commonly poffeffed by a number of small tenants; thus a farm of 40l. a-year is occupied by 18 different people, who by their leafes are bound, conjunctly and feverally, for the payment of the rent to the proprietor. These live in the farm in houses clustered together, so that each farm appears like a little village. The tenants annually divide the arable land by lot; each has his ridge of land, to which he puts his mark, fuch as he would do to any writing; and this species of farm is called runrig, (i. e.) ridge. They join in ploughing; every one keeps a horse or more; and the number of those animals confumes to much corn, as often to occasion a fearcity; the corn and peas raised being (much of it) defigned for their sublistence, and that of the cattle, during the long winter. The pasture and moor land annexed to the farm is common to all the possessors. All the farms are open. Enclosures of any form, except in two or three places, are quite unknown: fo that there must be a great loss of time in preserving their corn, &c. from trefpass. The usual manure is sea plants, coral and shells. The run-rig farms are now discouraged: but fince the tenements are fet by roup or auction, and advanced by an unnatural force to above double the old rent, without any allowance for enclosing, any example fet in agriculture, any fecurity of tenure by lengthening the leafes, affairs will turn retrograde. and the farms relapse into their old state of rudeness;

migration

ment.

migration will increase (for it has begun), and the Arrange- reuts be reduced even below their former value: the late rents were scarce 1200l a-year; the expected rents 3000l.

> "The produce of the illand is oats; of which about 5000 bolls, each equal-to nine Winchester bushels, are fown, 500 of beans, a few peas; and above 1000 bolls of potatoes, are annually fet: notwithstanding this, 500 bolls of oat meal are annually imported, to sublist the natives.

> "The live flock of the island is 3183 milch cows; 2000 cattle, from one to three years old; 1058 horses; 1500 sheep; and 500 goats: many of the two last are killed at Michaelmas and dried for winter-provision, or fold at Greenock. The cattle are fold from 40 to 50s. per head, which brings into the island about 1200l. per annum: I think that the sale of horses also brings in about 300l. Hogs were introduced here only two years ago. The herring-fishery round the island brings in 300l, the fale of herring-nets 100l, and that

> of thread about 300l. for a good deal of flax is fown here. These are the exports of the island; but the money that goes out for mere necessaries is a melancholy drawback.

> "The women manufacture the wool for the clothing of their families; they fet the potatoes, and drefs and spin the flax. They make butter for exportation, and cheefe for their own use.

> "The inhabitants in general are fober, religious, and industrious; great part of the summer is employed in getting peat for fuel, the only kind in use here; or in building or repairing their houses, for the badness of the materials requires annual repairs: before and after harvest, they are busied in the herring fishery; and during winter the men make their herring nets; while the women are employed in spinning their linen and woollen yarn. The light they often use is that of lamps. From the beginning of February to the end of May, if the weather permits, they are engaged in labouring their ground: in autumn they burn a great quantity of fern, to make kelp. So that, excepting at new-year's day, at marriages, or at the two or three fairs in that island, they have no leifure for any amusements: no wonder then at their depression of spirits.

> "Arran forms part of the county of Bute, and is fubject to the same fort of government: but, besides, justice is administered at the baron's bailie-court, who has power to fine as high as 20s.; can decide in matters of property not exceeding 40s.; can imprison for a month; and put delinquents into the flocks for three hours, but that only during day-time."

> In this island there are many of those rude antiquities or monuments called cairns, druidical circles, &c. See CAIRNS.

> ARRANGEMENT, or RANGEMENT, the disposition of the parts of a whole, in a certain order.

> The modern philosophy shows us, that the diversity of the colours of bodies depends entirely on the fituation and arrangement of the parts, which reflect the light differently; the diversity of tastes and smells on the different arrangements of the pores, which render them differently fenfible; and the general diversity of bodies on the different arrangement of their parts. The happy arrangement of words makes one of the greatest beauties of discourse.

ARRAS, the capital city of Artois, a province in the French Netherlands. It is sented on a mountain: and the parts about it are full of quarries, where they get stone for building. It is divided into two parts, the town and the city The abbé of St Vedast is lord of the town, and the bishop of Arras of the city, which is the least part. They are divided by a strong walla large fosse, and the little river Chrinchron, which 100 paces below falls into the Scarp. They are both well fortified, enclosed by high ramparts, and by double deep fosses, which in several places are cut out of the rock. It has four gates; and fince the French are become masters of it, has a strong citadel with five baltions. The most remarkable places are, the great fquare where the principal market is kept; this is full of fine buildings, with piazzas all round it like those of Covent-garden. Not far from this is the leffer market, which contains the town-house, a very noble structure, with a high tower covered with a crown, on the top of which is a brazen lion which ferves for a vane. In the midst of this market is the chapel of the Holy Candle, which the Papitls pretend was brought by the Virgin Mary herself above 600 years ago, when the city was afflicted with divers diseases, and every one that touched the candle was cured; it is kept in a filvershrine. This chapel has a spire sleeple, adorned with several statues. The cathedral church of Notre-Dame stands in the city: it is a very large Gothic building, extremely well adorned; the tower is very high, and has a fine clock embellished with little figures in bronze, which represent the passion of Jesus Christ; they pass before the bell to strike the hours and half hours. In this church there is a filver shrine, enriched with pearls and diamonds, which contains a fort of wool, which they call manne; that they fay fell from heaven in the time of a great drought, almost 1400 years ago: they carry it very folemnly in procession when they want rain. The abbey-church of St Vedast is the greatest ornament of Arras, it being adorned with a fine fleeple, and feats for the monks of admirable workmanship; the pulpit is of brafs, fashioned like a tree, supported by two bears of the same metal, fitting on their hind legs; there are little bears in different postures coming to climb up the tree. The chimes are remarkable for the different tunes which they play. There are 11 parish churches, and a great many convents of men and women. It is from this city that the tapestry called arras hangings takes its denomination. E. Long. 2. 56. N. Lat. 50. 17.

ARRAS, or Araxes, is also the name of a river of Georgia, which discharges itself into the Caspian sea.

ARRAY, in law, the ranking or fetting forth of a jury, or inquest of men impanelled on a canfe.

Battle-Array, the order or disposition of an army, drawn up with a view to engage the enemy. See ARMY.

ARRAYERS, or ARRAGERS, ARRAITORES, is used in so ne ancient statutes, for such officers as had care of the foldiers armour, and faw them duly accoutred in their kinds. In fome reigns, commissioners have been appointed for this purpose. Such were the commissioners of array appointed by King Charles I. in the year 1642.

ARREARS, the remainder of a fum due, or money remaining in the hands of an accountant. It likewife

figuifies

Arrears.

Arreit.

Arrents, figuifies the money due for reat, wages, &co. or what remains unpaid of pentions, taxes, &c.

ARRENTATION, in the forest laws, implies the licenfing the owner of lands in a forest to enclose them with a low hedge and a fmall ditch, in confideration of a yearly rent.

ARREST, in English law (from the French word arrefler, to flop or flay), is the restraint of a man's perfon, obliging him to be obedient to the law; and is defined to be the execution of the command of some court of record or office of justice. An arrest is the beginning of imprisonment; where a man is first taken, and reftrained of his liberty, by power or colour of a lawful warrant.

Arrests are either in civil or criminal cases.

1. An arrest in a civil cause is defined to be the apprehending or restraining one's person by process in execution of the command of some court.

An arrest must be by corporal seizing or touching the defender's body; after which the bailiff may jullify breaking open the house in which he is, to take him: otherwise he has no such power; but must watch his opportunity to arrest him. For every man's house is looked upon by the law to be his castle of defence and afylum, wherein he should suffer no violence. Which principle is carried fo far in the civil law, that, for the most part, not so much as a common citation or summons, much less an arrell, can be executed upon a man within his own walls. Peers of the realm, members of parliament, and corporations, are privileged from arrefts; and of course from outlawries. And against them the process to enforce an appearance must be by furnious and diffres infinite, instead of a capias. Also clerks, attorneys, and all other persons attending the courts of justice (for attorneys being officers of the court, are always supposed to be there attending) are not liable to be arrested by the ordinary process of the court, but must be sued by bill (called usually a bill of privilege), as being perfonally present in court. Clergymen performing divine fervice, and not merely flaying in the church with a fraudulent defign, are for the time privileged from arrefts, by flatute 50 Edw. III. c. 5. and 1 Rich. II. c. 16.; as likewise members of convocation actually attending thereon, by flatute 8 Hen. VI. c. 1. Suitors, witnesses, and other perfons, necessarily attending any courts of record upon business, are not to be arrested during their actual attendance, which includes the necessary coming and returning. Seamen in the king's service are privileged from arrefts for debts under 20l. (I Geo. II. c. 14. and 14 Geo. II. c. 38.); and foldiers or marines are not liable to arrefts for a debt of less than 10l. (30 Geo. II. c. 6. 11.) And no arrest can be made in the king's presence, nor within the verge of his royal palace, nor in any place where the king's justices are actually fitting. The king hath moreover a special prerogative (which indeed is very feldom exerted), that he may by his writ of protection privilege a defendant from all personal, and many real suits, for one year at a time, and no longer; in respect of his being engaged in his service out of the realm. And the king also by the common law might take his creditor into his protection, so that no one might sue or arrest him till the king's debt was paid : but by the flatute 25 Edw. III. c. 19. notwithstanding such protection, another credi-

tor may proceed to judgment against him, with a stay of execution, till the king's debt be paid; unless such creditor will undertake for the king's debt, and then he shall have execution for both. And, lastly, By statute 29 Car. II. c. 7. no arrest can be made, nor procefs ferved, upon a Sunday, except for treason, felony, or breach of the peace.

2. An arrest in a criminal cause is the apprehending or reftraining one's person, in order to be forthcoming to answer an alleged crime. To this arrest all persons whatfoever are, without distinction, equally liable; and doors may be broken open to arrest the offender: but no man is to be arrefted, unless charged with such a crime as will at least justify holding him to bail when taken. There is this difference also between arrests in civil and criminal cases, that none shall be arrested for debt, trespass, or other cause of action, but by virtue of a precept or commandment out of some court; but for treason, felony, or breach of the peace, any man may arrest with or without warrant or precept. But the king cannot command any one by word of mouth to be arrested; for he must do it by writ, or order of his courts, according to law: nor may the king arrest any man for suspicion of treason, or felony, as his subjects may; because, if he doth wrong, the party caunot have an action against him.

Arrests by private persons are in some cases commanded. Persons present at the committing of a selony must use their endeavours to apprehend the offender, under penalty of fine and imprisonment; and they are also, with the utmost diligence to pursue and endeavour to take all those who shall be guilty thereof out of their view, upon a hue and cry levied against By the vagrant act 17 Geo. II. c. 5. every person may apprehend beggars and vagrants; and every private person is bound to assist an officer requiring him to apprehend a felon.

In some cases likewise arrests by private persons are rewarded by law. By the 4 and 5 William and Mary, c. 8. persons apprehending highwaymen, and profecuting them to a conviction are entitled to a reward of 40l.; and if they are killed in the attempt, their executors, &c. are entitled to the like reward. By the 6 and 7 William III. c. 17. perfons apprehending counterfeiters and clippers of the coin, and profecuting them to conviction are entitled to 40l.

By 5 Ann, c. 31. perfons who shall take any one guilty of burglary, or the felonious breaking and entering any house in the day time, and prosecute them to conviction, shall receive the sum of 40l. within one month after fuch conviction.

With regard to arrefts by public officers, as watchmen, constables, &c. they are either made by their own authority, which differs but very little from the power of a private person; or they are made by a warrant from a justice of peace. See WARRANT.

ARREST of Judgment, in law, the affigning just reafon why judgment should not pass: as, Want of notice of the trial; a material defect in the pleading; when the record differs from the deed impleaded; when perfons are misnamed; where more is given by the verdict than is laid in the declaration, &c. This may be done either in criminal or civil cases.

ARRESTMENT, in Scots law, fignifies the fecuring of a criminal till trial, or till he find caution to

Arrefto fland trial, in what are called builable crimes. In civil cases, it signifies either the detaining of strangers, or Arrobas. natives in meditatione fuga, till they find caution judicio fifli, or the attaching the effects of a stranger in order to found jurisdiction. But, in the most general acceptation of the word, it denotes that diligence by which a creditor detains the goods or effects of his debtor in the hands of third parties till the debt due to him be either paid or secured. See Law, Part III. Nº clxxviii.

ARRESTO FACTO SUPER BONIS, &c. a writ brought by a denizen against the goods of aliens found within this kingdom, as a recompense for goods taken from him in a foreign country.

ARRESTS, in farriery, mangy tumours upon a horse's hinder legs, between the ham and the paflern.

ARRETIUM, (Cicero, Cæfar); Arrhetium, (Ptolemy); Urbs Arrhetinorum, (Polybius); one of the twelve ancient towns of Tufcany, near the Arnis and Clanis, fituated in a pleafant valley. Now Arezzo, 42 miles east of Florence. E. Long. 13. 18. Lat. 43.

ARRIIABONARII, a fect of Christians, who held that the eucharift is neither the real flesh or blood of Christ, nor yet the fign of them; but only the

pledge or carnell thereof.

ARRHEPHORIA, a feast among the Athenians, inflituted in honour of Minerva, and Herse daughter of Cecrops. The word is composed of agento, mystery, and piga, I carry; on account of certain mysterious things which were carried in procession at this solemnity .- Boys, or, as fome fay, girls, between feven and twelve years of age, were the ministers that assisted at this feast, and were denominated agenpogon. This feast was also called Hersiphoria, from the daughter of Cecrops, already mentioned.

ARRIAN, a famous philosopher and historian under the emperor Hadrian and the two Antonines, was born at Nicomedia in Bithynia. His great learning and eloquence procured him the title of The jacond Nenophon; and raised him to the most considerable dignities at Rome, even the confulfhip itself. We have four books of his Differtations upon Epidetus, whose scholar he had been; and his History of Alexander the Great, in feven books, is greatly admired by the best indges.

ARRIERE, the hinder or posterior part of any

ARRITRE Ban, in the French culloms, is a general proclamation, whereby the king fummons to the war all that hold of him, both his vallals, i. e. the nobleffe, and the vallals of his vallals.

ARRIERE Fee, or Fief, is a fee dependent on a fuperior one. These sees commenced, when the dukes and counts, rendering their governments hereditary in their families, diffributed to their officers parts of the royal domains which they found in their respective provinces, and even permitted those officers to gratify the foldiers under them in the same man-

ARROBAS, or Arobas, a weight used in Spain, Portugal, and the foreign dominions of both. arrobas of Portugal is also called Arata, and contains thirty-two Lisbon pounds; that of Spain contains Vol. II. Part 1.

ARROE, a small island of Denmark, in the Baltic Arsenic. fea, a little fouth of the island of Funen. It is eight miles in length, and about two in breadth; and produces corn, anifeed, black cattle, and horfes. It has three parishes, the most considerable of which is Koping. It stands at the fouth side of the island, in the bottom of a bay, and has a port with some trade. E. Long. 9. 40. N. Lat. 55. 20.

ARROJO, DE ST SERVAN, a town of Spain, in Estremadura. W. Long. 5. 20. N. Lat. 38. 40.

ARRONDEE, in heraldry, a cross, the arms of which are composed of sections of a circle, not oppofite to each other, fo as to make the arms bulge out thicker in one part than another; but the fections of each arm lying the same way, so that the arm is everywhere of an equal thickness, and all of them terminating at the edge of the escutcheon like the plain

ARROW, a missive weapon of offence, slender, pointed, and barbed, to be cast or shot with a bow. See ARCHERY.

Arrow-Makers are called fletchers; and were formerly, as well as bowyers, persons of great confequence in the commonwealth.

Arrow-heads and quarrels were to be well boched or brased, and hardened at the points with seel; the doing of which feems to have been the bufiness of the arrow-fmith.

ARRON-Head, in botany. See SAGITTARIA.

AKRON-Rost. See MARANTA.

ARSACES, otherwise MITHRIDATIS, a king of the Parthians, spoken of in the first book of Maccabees, xiv. 2. He confiderably enlarged the kingdom of Parthia by his good conduct and valour. Sec Par-

ARSCHIN, in commerce, a long measure used in China to measure stuffs. Four arschins make three yards of London.

ARSENAL, a royal or public magazine, or place appointed for the making and keeping of arms, necesfary either for defence or affault. Some derive this word from arx a fortrefs; others from ars, denoting a machine; others again from arx and fenatus, because this was the defence of the fenate: but the more probable opinion derives it from the Arabic darfinan, which fignifies arfenal.

The arfenal of Venice is the place where the galleys are built and laid up. The arfenal of Paris is that where the cannon or great guns are cail. It has thes inscription over the gate:

> Æina hær Henrico vulcania tela minificat, Tela Gigantæos debellatura furores.

There are arfenals, or store-houses, appropriated to naval furniture and equipments. At Marfedles is the arienal for the galleys; and at Toulon, Rochfort, and Breft, are those for the men of war.

ARSENIC, in mineralogy and chemistry, a heavy opaque fubitance, ufually fold in white mailes, which, when broken, discover a semi-transparency somewhat refembling that of fal ammoniac, but by exposure to the air become white and opaque like the outfide of the original mass. By various chemical processes it may Υy

be

Arbeit, be made to assume either the appearance of an acid falt or metal, at the pleasure of the operator; and therefore has been confidered both as a faline substance and as a figui-metal. It is not known at what time this. mineral was discovered; though, as it abounds in mamy different kinds of orce, it is probable that the pernicious properties it manifests would very foon make it be taken notice of by metallurgifts. Ariflotle makes mention of a substance called Eurdneany, and his disciple Theophraftus makes mention of one named Aggrees, which by Dioscorides and others was called Agormes, about the beginning of the Christian era. By this, however, it appears, that they only meant the substan-Is not men ces now called fandurach and orpiment; and Avicenna the time of who lived in the 11th century, is the first who express-Avicenna. ly mentions white arfenic, as well as its fublimate. It is not known by whom arfenic was full reduced to a metallic form. Paracelfus afferts that arfenic, fublimed with egg-shell lime becomes like silver; and, in 1675, M. Lemeri makes mention of a method of subliming arfenic with fixed alkali and foap.

The true nature of arfenic being thus fo little known, it is no wonder to find chemists differing very much as to the class of natural bodies in which it ought to be placed. Avicenna and a great number of others class it with the fulphurs; Albertus Magnus and his followers, among the falts. Becher confiders it as a kind of Composed foap, or faline fulphureous body. Later experiments, of an acid however, have made it evident, that white arfenic confifts and phlogifof an acid united to phlogiston; and that by diminishing the latter, the acid becomes more and more apparent; while, on the contrary, by augmenting the quantity of phlogistic matter, the arsenic assumes the metallie form. With respect to the sulphurcous nature of arfenic, it appears, indeed that the regulus itself, as well as orpiment and realgar, are inflammable substances; but it is not fo with white arfenic. This inflammability, therefore, which arfenic in a certain flate has in common with zinc and feveral other fubitances, will

not denominate it sulphureous, any more than those of

other bodies which possels the common property of inflammability can be denominated fulphurs.

Is not to be berehdans Ls a fub-

ton.

It is commonly faid, that affenie mineralizes metals; and therefore, fays Mr Bergman, it is confidered as a fulphur by fome, who yet extend the idea of mineraliwhen other zation fo far, as under it to comprehend all mixtures tetal are of which metals make a part. But if we examine this n metalize fignification a little more accurately, we shall see that it is extended too far; for if this be admitted, we must at the same time allow, that no native metal is to be found. Thus the gold called native, is feldom if ever found pure, but more or less mixed with copper or filver g and fo with other metals. If, therefore, arfenic, which, unless in its reguline flate, never dissolves other metals, he confidered as a mineralizing fubstance, what hinders us from faying that gold is mineralized by filver or copper, and in general every metal mineralized by fome other? It is much more natural to suppose that those metals are mineralized which are actually disfolv-Sulphur the ed and conocaled by a menstruum. Sulphur is the chief mine chief agent employed by nature for this purpole; and though the acids of vitrol, phosphorus, sitre, and fornetimes even the aerial acid, occasion the metals to put on an appearance foreign to their nature, vet the

sumber of these is so small, that, compared with the ful- Arsenie. phurated minerals, they almost vanish.

This mineral, fo troublesome to the mineralogist, 5 occasioned the alchemists to suspect the existence of a An arienic certain arienical principle indispensably necessary to the capte erroperfection of every metal. Even as late as 1773 a nously supquestion to this purpose was proposed by the Royalpoid necessary Academy of Sciences at Berlin: the prize was adjudg-fary for the ed to M. Monnet, who in his answer considered perfection arsenic as a semi-metal of a peculiar kind, which is fo far from constituting any essential part of metals, that its presence is always attended with inconvenienccs, either by carrying off the metal as it flies away, or spoiling the mass in which it remains. These considerations, however, do not hinder us from afferting that Acid of the acid of arfenic, like others, is a mineralizing fub-arfenic a stance, if at any time it happens to meet with metals mineralizin the bowels of the earth, and to unite with it in that flunce

Arfenic in its pure state is well known to be a most Possonous destructive and deadly poison, for which the art of mc-9' lines of dicine has scarcely as yet afforded a cure. Mr Beig-arienc and man is of opinion that it acts as an highly corrolive acid, even when applied externally. He also tells us, that the dry send is more destructive than white arienic; the regulus and realgar less fo. From an experiment of Mr Scheele, however, in which eight grains of arfenical acid were given to a cat, it does not appear that it acts more violently than white aifenic. The extreme danger attending this substance when ta-Why it is ken into the human body, arises from its infolubility, more danand the difficulty of decompounding it; for there can gerous than but little danger arise from a liquid, unless like corro-others. five acids, it should at once burn the substance of the flomach like fire; or, like laurel water suspend the action of the nervous system. Corrosive sublimate, solutions of mercury in aquafortis, &c. will as certainly poison as arfenic; but they are much less difficult to cure, because any alkaline substance will certainly decompound them and destroy their descretious efficacy. Arfenic, on the contrary, cannot be decompounded, nor united with any known fubflance, at least in fuch a short time as the exigence of the case we speak of would require, without a confiderable degree of heat. It therefore remains in the stomach, continually exerting its mischievous qualities, unless it can be discharged by vomiting.

The fymptoms attending arfenic when swallowed Symptom's are, nausea, sickness, and retching to vomit, about half attending an hour after it is taken. These are followed by vio-the Iwal lent vomitings, hiccups, and pains in the stomach and allenic. bowels. Convultions and palties of the limbs prefently fucceed, with intense heats, cold sweats, palpitations of the heart, extreme anxiety, profiration of firength, thirst and dryness of the mouth and throat, loss of reafon, and at last death. If the quantity taken was considerable, the patient dies in seven or eight hours after taking it; and the flomach and intestines are found, upon diffection, to be corroded and perforated. When this is not the case, violent putrefactive symptoms foon enfue after arfenic is swallowed; for the bodies of those who are poisoned by it generally have abundance of red or purple spots even before death. It remarkably inflames the coats of the stomach, and the putre-

faction

to ken of m als.

Arienic. fuction is faid particularly to take place in the genitals of men. Mr Bergman relates, that in the body of a man who was poisoned with arlenic, and diffected in the anatomical theatre at Upfal, the putrefaction had been fo strong that the mineral was deprived of part of its phlogiston, and emitted the garlic smell, that peculiar characteristic of arsenic when in this situation.

10 Antidates

Many antidotes have been proposed against this ineffectual- dreadful poison by authors of the highest reputation; ly proposed but it is to be feared without that success which the confidence of those who proposed them seemed to cafure. Indeed, previous to any great hope of fuccess in this respect, it ought to be shown that these antidotes are able to effect fome confiderable change on arfenic when out of the body; and that not in solution, but when in a powder not very fine, as is the cafe with arfenic when it is usually taken. Mr Bergman recommends alkalis in diseases occasioned by arsenic: Nay he tells us, that " fince phlogiston and alkalis are the most powerful correctors of acid acrimony, it will readily occur, how it may be mitigated, and its deleterious effects obviated." But the many fatal accidents consequent on taking this mineral, show that none of those are to be depended upon. Bergman himself indeed cautions us against trusting to phlogiston correctors alone; and perhaps the folution of hepar fulphuris, which contains the united powers of both the alkaline and phlogistic antidotes united, might prove more esticacious than either of them fingly. Oils, fats, milk, werm fat broths, fresh butter, &c. have all been recommended; and, no doubt, in fuch deplorable cases, are those remedies to which we can most readily have recourse: but even here it is evident, that their efficacy must be exceedingly dubious, whatever their intrinsic virtues may be; and for this plain reason, that the arscnic is already in contact with the stomach, and though the remedies might have prevented its action had they been first swallowed, their operation must be much less powerful after the poison has had access to the flomach and begun to exert its pernicious effects.

Notwithstanding these dreadful effects of arsenic when taken in large quantity, attempts have not ed as a me-been wanting to introduce it into the materia medica.

The difease indeed in which they have been recommended (the cancer) is of a very incurable nature, at least by ordinary medicines. M. le Febure, a French physician, some time ago published a treatise, in which he recommended pure white arienic as a specific in that distemper. The dose was four French grains, equal to 31 English, dissolved in a French pint (32 troy ounces) of distilled water. A table spoonful of this folution is to be taken with an equal quantity of milk, and half an ounce of fyrup of poppies, every morning fasting, and taking care to taste nothing for an hour after. This course must be continued eight days; after which a dose is to be taken twice every day in the fame manner, one in the morning and another about eight at night. At the end of a fortnight three doses may be exhibited daily, the third being taken at mid-day. Thus people of a weakly conflitution may continue till the cure is completed; but such as are more robust may gradually augment the dose till two table spoonfuls are taken at each time with as much milk, and half an ounce of fyrup of poppies. Children

must on no account take more than three teaspoonfuls. Articies a-day, with a proportional quantity of fyrup of poppies. For adults, the strength of the folution, as well as the quantity, is to be augmented; fix grains being put into the second bottle and eight into the third; and a purgative composed of manna, rhubarb, and fal feignette, is to be given every eight or twelve days. An issue he considers as useful in every case. The tumor, if not ulcerated, ought to be washed with a folution of arfenic in the proportion of eight grains to a pint; and he advises the following cataplasm: " Take of carrot juice, one pound; of fugar of lead, half an ounce; of arfenic, diffolved in diffilled vinegar, half an ounce; of liquid laudanum, a drachm and a half: form the whole into a mass with as much powder of hemlock as is fufficient for the purpose. The tumour is to be covered to a moderate thickness with this cataplasm, which is to be kept on by a diachylon plaster." When the cancer is of the ulcerated kind, he directs the ichorous ferofity to be taken away by means of dry charges at each dreffing, and the fore to be formented with the arfemical folution with the chill taken off it, and having about a third part of red wine added to it. When the fore is of a very bad kind, he proposes the arlenic to be dissolved in decoction of bark for the purpose of fomentation; after which the cataplasm and plaster are to be applied, and this is to be renewed every twelve hours.

M. Le Febure afferts, that the arfenic, when taken with the precautions just mentioned, is not attended with any bad confequences, nor has it a difagreeable tafte. Its action is scarcely perceived on any of the fecretions or excretions; though fome discharge their urine more freely than usual, and with some the belly is more loofe. In some the perspiration is more copious; but these effects are neither regular nor conflant. He does not confider it as an infallible cure for the distemper in every possible stage; but thinks that the disease is incurable, when, in its progress, it has eroded a blood veffel, and occasioned a considerable hemorrhagy; also when the patient is of a hectic or phthifical habit of body. With respect to regimen, he directs whey, with twelve grains of nitre to the bottle, or a weak decoction of althea with an equal quantity of nitre; and to abstain from wine and fermented liquors. Broth made with beef, yeal, or chicken, is alfo proper.

Mr Bergman informs us, "that it can hardly be Mr Bergdoubted but arfenic may be applied to valuable pur-man's opipofes in medicine, and experiments have long ago put nionthat out of doubt; but with respect both to its dose and preparation, the utmost caution is necessary."

Dr Black, however, has feen the internal exhibition The mterof arfenic, in those cases where it is recommended by nal exhibiforeign physicians, attended with very dangerous con tion of artfequences, such as hectics, &c. He has likewise me an pknown obstinate ulcers healed by it. Yet though the proved by external use of arsenic has proved successful in some by Black. cases, it has often, even in this way, produced very terrible consequences: so that the Doctor, far from recommending the internal use of it, reprobates it even in external applications.

As physicians are often called in cases where it is fulpected that people have died from the effects of ar-

Arfenie recommend. internally and externally.

Arfenic. Lactures on employeds .. Chemiffry.

xôt when cales of ar-

fenic taken internally, Doctor Black gives the following directions to the phylician who happens to be thus

" He should answer every question put to him with Directions caution, as the lives and reputations of many often de-

to a physi- pend on his opinions. "The first question usually put is, Whether, from the symptoms of the patient, or the appearance of the body after death, he imagines the deceafed died by befenic being ing poisoned with arsenic? The symptoms attending swallowed, the taking of arsenic are, in about a quarter of an hour, fickness at stomach, succeeded by vomiting, purging, burning pain in the bowels, heat and thirst, pains and cramps in the legs and thighs, fyncope, and death. When the body is examined, the intestines appear inflamed and corroded; nay, fome ulcerations appear about the anus even before death. But we must take care not to be deceived by erofions of the flomach occasioned by the gastric juice, which has a power of diffolving the flomach after death. The difference is that the arfenic occasions inflammation and blackness, whereas none appears in the other case. If the person cscapes, he is in danger of being afflicted by marasmus, paralytic affections of the limbs, great debility, &c.

"The second question generally asked is, Whether any arfenic has been found in the intestines? The method of discovering this is as follows: The contents of the stomach and intestines should be taken out and washed in water; and any powder it contains suffered to separate. If any arsenic be mixed with it, it will fall to the bottom, and must then be examined by the fol-

lowing methods:

" I. By laying it on a red hot iron. If it be arfenic, it will evaporate, without melting, in a thick white vapour; and this may be shown by the 40th part of a grain.

" 2. We may mix fome of it with charcoal; in which state, if it be arsenic, it will emit an odour very like garlie; but this will not be perceived unless it be mixed with charcoal or some inflammable matter.

" 3. We may enclose the powder with some charcoal, between two polished bits of copper, the edges of which are moistened with a lute made of two parts of fine fand and one of pipe clay. The plates being then bound together with a wire, and the whole made red hot, the arfenical powder will thus be metallized, and, penetrating the copper, a blackish skin will first appear upon it; which being rubbed off, the parts which the arfenical vapour has touched will appear of a whitish or lead colour.

" 4. We may metallize or reduce the arfenic in a glass tube, by means of the black flux. This is easily done by mixing two or three parts of the flux with one of the powder. This mixture being put into a small glass tube, and a heat applied sufficient for volatilizing the arfenic, the greatest part of it will be metallized. One end of the tube is to be left open at first, and then stopped with lint or wool; the other made red hot; and if the tube be then broken, the arfenic is found metallized. One grain of arfenic will be fufficient Ill those experiments."
The first fymptoms which ensue on the taking of ar-

ferie flow that it is of a highly inflammatory, caustic, and prrofive nature, with regard to the fystem in general, and the intestines in particular: the pulse be- Arsenie. comes extremely weak and irritable, and this is attended ' with a kind of paralytic affection of the limbs, marafmus, &c. Milk and oil have been recommended as antidotes: but the milk may curdle, and the oil will not mix with the fluids in the intestines. It is therefore advisable, when a physician is called to a patient who has swallowed arlenic, to make use of mucilages. A friend of Dr. Black's, who had no mucilage at hand, thought of the whites of eggs, and succeeded. After the violence of the first attack is over, a milk diet, opiates, &c. are proper; and some time after, electricity has been found of great service. Some have advifed to exhibit hepar fulphuris, as already noticed: but this is founded, not on experience, but theory; and it cannot be supposed that such a quantity can enter the fystem as will be sufficient for neutralizing the arfenic, and coverting it into orpiment, which is the defign of exhibiting it.

Notwithstanding, however, the very violent effects of arlenic, it has been employed in the cure of diseases, both as applied externally and as taken internally. Externally, white arfenic has been chiefly employed in cases of cancer; and as used in this way, it is supposed that its good effects depend on its acting as a peculiar corrofive: and it is imagined, that arfenic is the basis of a remedy long celebrated in cancer, which, however, is flill kept a fecret by a family of the name of Plunket in Ireland. According to the best conjectures, their application confils of the powder of fome vegetables, particularly the ranunculus flammens and cotula foctida, with a confiderable proportion of arfenic and flower of fulphur intimately mixed together. This powder, made into a paste with the white of an egg, is applied to the cancerous part which it is intended to corrode; and being covered with a piece of thin bladder, fmeared also with the white of an egg, it is fuffered to lie on from 24 to 48 hours; and afterwards the eschar is to be treated with softening digestive, as in other cases.

Arfenic, in substance, to the extent of an eighth of a grain for a dofe, combined with a little of the flowers of fulphur, has been faid to be employed internally in some very obstinate cases of cutaneous diseases, and with the best effect. But of this we have no experience.

Of all the diseases in which white arsenic has been used internally, there is no one in which it has been so frequently and fo fuccessfully employed as in the cure of intermittent fevers. It has long been used in Lincolnshire, and some other of the fenny countries, under the name of the arfenic drop, prepared in different ways: And it is conjectured, that an article, which has had a very extensive sale, under the title of the tasteless aguedrop, the form of preparing which, however, is fill kept a fecret, is nothing else but a solution of arsenic. But whether this be the case or not, we have now the most fatisfactory information concerning this article in the "Medical Reports, of the effects of Arfenic in the cure of agues, remitting fevers, and periodic head-achs," by Dr Fowler of Stafford. He directs, that 64 grains of arfenic, reduced to a very fine powder, and mixed with as much fixed vegetable alkaline falt, should be added to half a pound of distilled water in a florence flask; that it should be then placed in a sand-

Arfenic heat, and gently boiled till the arfenic be completely dissolved; that after the folution is cold, half an ounce of compound spirit of lavender be added to it, and as much distilled water as to make the whole folution amount to a pound. This folution is taken in doses. regulated according to the age, firength, and other circumstances of the patient, from two to twelve drops, once, twice, or oftener in the course of the day. And in the discases mentioned above, particularly in intermittents, it has been found to be a fafe and very efficacious remedy, both by Dr Fowler and by other practitioners: but in fome inflances, even when given in very fmall doses, we have found it excite violent vomiting. But belides this, it has also been alleged by fonc, that those cured of intermittents by arfenic are very liable to become phthifical. If arfenic shall ever be extensively employed internally, it will probably be most certain and most fafe in its operation when brought to the flate of a falt readily foluble in water."

Philosophers are wont to evince the extraordinary porofity of bodies, and the wonderful fubtilty of vapours, by a fympathetic ink made with orpiment and See Sym- lime *; for writing made with vinegar of litharge, by itfelf invifible, exposed to the vapour of this liquor becomes in a few minutes brown, even though a great

many folds of paper be interposed.

16 If the af wines.

f arfenic.

athetic

Wines naturally acid, or grown to by age, still ulteration continue to be edulcorated by lead, notwithstanding the punishments attending the detection of this fraud: it is therefore of great confequence to be in possession of an eafy method of discovering such a sophistication. For this purpose a probatory liquor has been recommended, composed of caustic fixed alkali and orpiment; which instantly throws down a black or dark brown precipitate, in confequence of the union of the sulphur of the orpiment with the metal. The same essect will take place on the addition of common hepar fulphuris; but methods have been contrived of eluding this proof. If a small quantity of chalk be contained in the wine, the faline hepar does not produce the intended effect; for the falling of the white calcareous earth diminishes the blackness. The other probatory liquor is also rendered ineffectual by a large quantity of tartar; because the tartareous acid, uniting with the lime, forms a kind of felenite, which in like manner diminishes the blacknefs.

Arfenic in omposiion with

Arfenic fometimes enters metallic compositions, especially copper and tin; but it were much to be wished that such compositions were banished, at least netals, &c. from the kitchen. Shot made of lead is fometimes hardened by orpiment.

Regulus of arlenic enters into the composition of Meuder's phosphorus. The power of the calx in vitrification was long ago known to Geber; and it is frequently employed in glass houses, either for facilitating fulion, for acquiring a certain degree of opacity, or finally for carrying off phlogitton. The method in which mountain cryffals, placed over orpiment, white arfenic, crude antimony, and fal ammoniac, mixed in a crucible, are tinged by means of heat, is described by Neri, and upon trials is found to be true.

" In painting too, the artifts, fometimes employ arfenic. Painters in oil frequently use Loth orpiment and realgar; and it is probable that wood covered with

a pigment mixed with white arfenic would not be Arfenic spoiled by worms. A most beautiful green pigment may be precipitated from blue vitriol by means of Artinoc. white arfenic diffolved in water, together with vegetable alkali. This prepared either with water or oil. affords a colour which fuffers no change in many years. The playthings of children, however, should not be painted with this or any other preparation of arfenic, on account of their cultom of putting every thing into their mouths."

Arfenic is also used in dying, and the yellow combination of it with fulphur has the property of readily diffolving indigo; for which purpose it is used in cloth printing. It lets it fall again, however, on exposure to the air; and therefore can be employed only in pencil colours, where a large quantity is laid on at once. The neutral arfenical falt is used in some manufactures in France; but for what purposes is not known.

ARSENIUS, a deacon of the Roman church, of great learning and piety. He was pitched upon by the pope to go to the emperor Theodofius, as tutor to his fon Arcadius. Arfenius arrived at Conftantinople in the year 383. The emperor happening one day to go into the room where Arfenius was inflructing Arcadius, his fon was feated and the preceptor standing; at this he was exceedingly displeased, took from his son the imperial ornaments, made Arfenius fit in his place, and ordered Arcadius for the future to receive his leffons standing uncovered. Arcadius, however, profited but little by his tutor's instructions, for some time after he formed a defign of despatching him. The officer to whom Arcadius had applied for this purpose, divulged the affair to Arlenius, who retired to the deferts of Scete, where he passed many years in the exercifes of the most strict and servent devotion. He died there, at 95 years of age.

ARSHOT, a town of the Austrian Netherlands, fituated about 14 miles call of the city of Mechlin, in

E. Long. 4. 45. N. Lat. 51. 5.

ARSINOE, (anc. geog.), a town of Egypt, on the west side of the Arabian gulf, near its extremity, to the fouth of Hicropolis, (Strabo, Ptolemy); called Cleopatris by fome. Another Arfinoc, a town of Cilicia, (Ptolemy); and the fifth of that name in Cilicia, (Stephanus); with a road or flation for ships, (Strabo). A third Arfinoe, in the fouth of Cyprus, with a port between Citium and Salamis, (Strabo). A fourth, an inland town of Cyprus, called Marium formerly, (Stephanus). A fifth in the north of Cyprus, between Acamas and Soli, (Strabo); so called from Arsinoc, a queen of Egypt, Cyprus being in the hands of the Ptolemies. A fixth Arfinoe, a maritime town of Cyrene, formerly called Teuchira. A feventh Arfinoe, in the Nomos Arfinoites, to the west of the Heracleotes, on the western bank of the Nile, formerly called Crocodilorum Urbs, (Strabo); the name Arfinee continued under Adrian, (Coin). Ptolemy calls this Arfinoe an inland metropolis, and therefore at fome diffance from the Nile, with a port called Ptolemair. An eighth Arfinoe, a maritime town of Lycia; fo called by Ptolemy Philadelphus, after the name of his confort, which did not hold long, it afterwards recovering its ancient name Patara, (Strabo). A muth, a town of the Troglodyre, near the mouth of the Arabian gulf, which to-

wards Ethiopia is terminated by a promontory called Birr, (Ptolemy). This Arthune is called Berenice, and the third of that name in this quarter, with the diffinction Epideres; because fituated on a neck of land running out a great way into the fea.

ARSIS and THESIS, in music, is a term applied to compositions in which one part rifes and the other falls.

ARSMART in botany. See Persicaria.

ARSON, in English law, is the malicious and wilful burning of the house or outhouse of another man; which is felony at common law.

This is an offence of very great malignity, and much more pernicious to the public than simple theft: because, first, it is an offence against that right of habitation which is acquired by the law of nature as well as by the laws of fociety; next, because of the terror and confusion that necessarily attends it; and, lastly, because in simple theft the thing stolen only changes its master, but still remains in effe for the benefit of the public; whereas by burning the very fubstance is abfo-lutely destroyed. It is also frequently more destructive than murder itself, of which too it is often the cause: fince murder, atrocious as it is, seldom extends beyond the felonious act defigned, whereas fire too frequently involves in the common calamity persons unknown to the incendiary, and not intended to be hurt by him, and friends as well as enemies.

ARSURA, in ancient cultoms, a term used for the melting of gold or filver, either to refine them, or to examine their value.-The method of doing this is explained at large in the Black Book of the Exchequer, afcribed to Gervaise, in the chapter De Officio Militis Argentarii, being in those days of great use, on account of the various places and different manners in

which the king's money was paid.

ARSURA, is also used for the loss or diminution of the metal in the trial. In this fense, a pound was said tot ardere denarios, to lose so many pennyweights.

ARSURA is also used for the dust and sweepings of filversmiths, and others, who work in filver, melted

ART is defined by Lord Bacon, A proper disposal of the things of nature by human thought and experience, fo as to answer the several purposes of mankind; in which fense art stands opposed to nature.

Art is principally used for a system of rules serving to facilitate the performance of certain actions; in which fense it stands opposed to science, or a system of

fpeculative principles.

Arts are commonly divided into useful or mechanic, liberal or polite. The former are those wherein the hand and body are more concerned than the mind; of which kind are most of those which furnish us with the necessaries of life, and are popularly known by the name of trades; as baking, brewing, carpentry, smithery, weaving, &c .- The latter are fuch as depend more on the labour of the mind than that of the hand; they are the produce of the imagination, their essence consists in expression, and their end is pleasure. Of this kind are poetry, painting, music, &c.

Progress of the ARTS. Some useful arts must be nearly coeval with the human race; for food, clothing, and habitation, even in their original simplicity, require some art. Many other arts are of such antiquity as to place the inventors beyond the reach of tradition. Several have gradually crept into the world without an inventor. The buly mind, however, accustomed to a beginning in things, cannot rest till it finds or imagines a beginning to every art. The most probable conjectures of this nature the reader may see in the historical introductions to the different articles.

and

In all countries where the people are barbarous and progress of illiterate, the progress of arts is extremely flow. It is useful arts. vouched by an old French poem, that the virtues of the Kames's loadstone were known in France before anno 1180. Sk. V.1 The mariner's compais was exhibited at Venice anno 1260, by Paulus Venetus, as his own invention. John Goya of Amalphi was the first who, many years afterward, used it in navigation; and also passed for being the inventor. Though it was used in China for navigation long before it was known in Europe, yet to this day it is not so perfect as in Europe. Instead of sufpending it in order to make it act freely, it is placed upon a bed of fand, by which every motion of the ship disturbs its operation. Hand-mills, termed querres, were early used for grinding corn; and when corn came to be raifed in greater quantity, horfe-mills fucceeded. Water-mills for grinding corn are described by Vitruvius. Wind-mills were known in Greece and in Arabia as early as the seventh century; and yet no mention is made of them in Italy till the fourteenth. That they were not known in England in the reign of Henry VIII. appears from a household book of an earl of Northumberland, cotemporary with that king, stating an allowance for three mill horses, " two to draw in the mill, and one to carry stuff to the mill and fro." Water-mills for corn must in England have been of a later date. The ancients had mirror-glasses, and employed glass to imitate crystal vases and goblets; yet they never thought of using it in windows. In the 13th century, the Venetians were the only people who had the art of making crystal glass for mirrors. A clock that strikes the hours was unknown in Europe till the end of the 12th century. And hence the cufrom of employing men to proclaim the hours during night; which to this day continues in Germany, Flanders, and England. Galileo was the first who conceived an idea that a pendulum might be useful for meafuring time; and Huygens was the first who put the idea in execution, by making a pendulum clock. Hook, in the year 1660, invented a spiral spring for a watch, though a watch was far from being a new invention. Paper was made no carlier than the 14th century; and the invention of printing was a century later. Silk manufactures were long established in Greece before silkworms were introduced there. The manufacturers were provided with raw filk from Persia: but that commerce being frequently interrupted by war, two monks, in the reign of Jultinian, brought eggs of the filkworm from Hindostan, and taught their countrymen the method of managing them. The art of reading made a very flow progress. To encourage that art in England, the capital punishment for murder was remitted if the criminal could but read, which in law language is termed benefit of clergy. One would imagine that the arts must have made a very rapid progress when fo greatly favoured: but there is a fignal proof

Arts. of the contrary: for so small an edition of the Bible as 600 copies, translated into English in the reign of Henry VIII. was not wholly fold off in three years. The people of England must have been profoundly ignorant in Queen Elizabeth's time, when a forged clause added to the 20th article of the English creed passed

unnoticed till about 50 years ago.

The discoveries of the Portuguese in the west coast of Africa is a remarkable inflance of the flow progress of arts. In the beginning of the 15th century, they were totally ignorant of that coast beyond Cape Non, 28 deg. north latitude. In 1410, the celebrated Prince Henry of Portugal fitted out a fleet for discoveries, which proceeded along the coast to Cape Bojadore in 26 deg. but had not courage to double it. In 1418, Triftan Vaz discovered the island Porto Santo; and the year after, the island Madeira was discovered. In 1439, a Portuguese captain doubled Cape Bojadore; and the next year the Portuguese reached Cape Blanco, lat. 20 deg. În 1446, Nuna Triftan doubled Cape de Verd, lat. 14. 40. In 1448, Don Gonzallo Vallo took possession of the Azores. In 1449, the islands of Cape de Verd were discovered for Don Henry. In 1471, Pedro d'Escovar discovered the island St Thomas and Prince's island. In 1484, Diego Cam discovered the kingdom of Congo. In 1486, Bartholomew Diaz, employed by John II. of Portugal, doubled the Cape of Good Hope, which he called Cabo Tormentofo, from the tempetuous weather he found in the passage.

Caules which advance the progress of arts.

The exertion of national spirit upon any particular art, promotes activity to profecute other arts. The Romans, by constant study, came to excel in the art of war, which led them naturally to improve upon other arts. Having, in the progress of society, acquired fome degree of taile and polish, a talent for writing broke forth. Nevius composed in verse seven books of the Punic war; belides comedies, replete with bitter raillery against the nobility. Ennius wrote annals, and an epic poem. Lucius Andronicus was the father of dramatic poetry in Rome. Pacuvius wrote tragedies. Plautus and Terence wrote comedies. Lucilius composed fatires, which Cicero escems to be slight and void of erudition. Fabius Pictor, Cincius Alimentus, Pifo Frugi, Valerius Antias, and Cato, were rather annalists than historians, confining themselves to naked facts, ranged in order of time. The genius of the Romans for the fine arts was much inflamed by Greek learning, when free intercourfe between the two nations was opened. Many of those who made the greatest figure in the Roman state commenced authors; Cafar, Cicero, &c. Sylla composed memoirs of his own transactions, a work much effeemed even in the days of Plutarch.

The progress of art seldom fails to be rapid, when a people happen to be roufed out of a torpid state by fome fortunate change of circumstances. Prosperity, contrasted with former abasement, gives to the mind a fpring, which is vigoroufly excrted in every new purfuit. The Athenians made but a mean figure under the tyranny of Pinistratus: but upon regaining freedom and independence, they were converted into heroes. Miletus, a Greek city of Ionia, being destroyed by the king of Persia, and the inhabitants made flaves, the Athenians, deeply affected with the misery of their brethren, boldly attacked the king in his own dominions, and burnt the city of Sardis. In less than

10 years after, they gained a fignal victory at Marathon; and, under Themislocles, made head against that prodigious army with which Kerkes threatened utter ruin to Greece. Such prosperity produced its usual effects: arts flourished with arms, and Athens became the chief theatre for sciences, as well as for fine arts. The reign of Augustus Cæsar, which put an end to the rancour of civil war, and restored peace to Rome, with the comforts of fociety, proved an auspicious era for literature; and produced a cloud of Latin historians, poets, and philosophers, to whom the moderns are indebted for their tafte and talents. One who makes a figure roufes emulation in all: one catches fire from another, and the national spirit is everywhere triumphant: claffied works are composed, and useful discoveries made in every art and science. With regard to Rome, it is true, that the Roman government under Augustus was in effect despotic: but despotism, in that fingle instance, made no obstruction to literature, it having been the politic of that reign to hide power as much as possible. Againilar revolution happened in Tufcany about three centuries ago. That country having been divided into a number of small republics, the people excited by mutual hatred between Imall nations in close neighbourhood, became ferocious and bloody, flaming with revenge for the flightest offence. Thefe republies being united under the great duke of Tulcany, enjoyed the fweets of peace in a mild government. That comfortable revolution, which made the deeper impression by a retrospect to recent calamities, roufed the national fpirit, and produced ardent application to arts and literature. The refloration of the royal family in England, which put an end to a cruel and envenomed civil war, promoted improvements of every kind; arts and industry made a rapid progress among the people, though left to themselves by a weak and fluctuating administration. Had the nation, upon that favourable turn of fortune, been bleffed with a fuccession of able and virtuous princes, to what a height might not arts and fciences have been carried! In Scotland, a favourable period for improvement was the reign of the first Robert, after shaking off the English yoke; but the domineering spirit of the feudal system rendered abortive every attempt. The refloration of the royal family mentioned above, animated the legiflature of Scotland to promote manufactures of various kinds: but in vain; for the union of the two crowns had introduced despotism into Scotland, which sunk the genius of the people, and rendered them heartless and indolent. Liberty, indeed, and many other advantages, were procured to them by the union of the two kingdoms; but the falutary effects were long fuspeaded by mutual enmity, such as commonly subfilts between neighbouring nations. Enmity wore out gradually, and the eyes of the Scots were opened to the advantages of their prefent condition; the national fpirit was roufed to emulate and to excel: talents were exerted, hitherto latent; and Scotland at prefent makes a figure in arts and fciences above what it ever made while an independent kingdom.

Another cause of activity and animation, is the being engaged in some important action of doubtful event; a struggle for liberty, the refisting a potent invader, or the like. Greece, divided into fmall states frequently at war with each other, advanced literature Arts. and the fine arts to unrivalled perfection. The Corficans, while engaged in a perilous war for defence of their liberties, exerted a vigorous national spirit; they founded a university for arts and sciences, a public library, and a public bank. After a long stupor during the dark ages of Christianity, arts and literature revived among the turbulent flates of Italy. The Royal Society in London, and the Academy of Sciences in Paris, were both of them instituted after civil wars that had animated the people and roufed their activity.

As the progress of arts and sciences toward perfection is greatly promoted by emulation, nothing is more fatal to an art or science than to remove that spur, as where some extraordinary genius appears who soars above rivalship. Mathematics seem to be declining in Britain; the great Newton, having surpassed all the ancients, has not left to the moderns even the faintest hope of equalling him; and what man will enter the

lists who despairs of victory?

In a country thinly peopled, where even necessary arts want hands, it is common to fee one person exercifing more arts than one: in feveral parts of Scotland, one man ferves as a physician, furgeon, and apothecary. In every populous country, even simple arts are split into parts, and each part has an artist appropriated to it. In the large towns of ancient Egypt, a physician was confined to a single disease. In mechanic arts that method is excellent. As a hand confined to a fingle operation becomes both expert and expeditious, a mechanic art is perfected by having its different operations distributed among the greatest number of hands: many hands are employed in making a watch, and a still greater number in manufacturing a web of woollen cloth. Various arts or operations carried on by the fame man, invigorate his mind, because they exercise different faculties; and as he cannot be equally expert in every art or operation, he is frequently reduced to supply want of skill by thought and invention. Constant application, on the contrary, to a fingle operation, confines the mind to a fingle object, and excludes all thought and invention: in fuch a train of life, the loperator becomes dull and flupid, like a beaft of burden. The difference is vifible in the manners of the people: in a country where, from want of hands, feveral occupations must be carried on by the same person, the people are knowing and converfable: in a populous country, where manufactures flourish, they are ignorant and unfociable. The same effect is equally visible in countries where an art or manufacture is confined to a certain class of men. It is visible in Indostan, where the people are divided into calls, which never mix even by marriage, and where every man follows his father's trade. The Dutch lint-boors are a fimilar inftance: the fame families carry on the trade from generation to generation; and are accordingly ignorant and brutish even beyond other Dutch peafants. The inhabitants of Buckhaven, a sea port in the county of Fife, were originally a colony of foreigners, invited hither to teach our people the art of fishing. They continue fishers to this day, marry among themselves, have little intercourse with their neighbours, and are dull and stupid to a proverb.

Useful arts paved the way to fine arts. Men upon the jine arts. whom the former had bestowed every convenience,

turned their thoughts to the latter. Beauty was fludied in objects of fight; and men of taile attached themselves to the fine arts, which multiplied their enjoyments, and improved their benevolence. Sculpture and painting made an early figure in Greece; which afforded plenty of beautiful originals to be copied in these imitative arts. Statuary, a more simple imitation than painting, was fooner brought to perfection: the statue of Jupiter by Phidias, and of Juno by Polycletes, though the admiration of all the world, were executed long before the art of light and shade was known. Apollodorus, and Zeuxis his disciple, who flourished in the 15th Olympiad, were the first who figured in that art. Another cause concurred to advance statuary before painting in Greece, viz. a great demand for statues of their gods. Architecture, as a fine art, made a slower progress. Proportions, upon which its elegance chiefly depends, cannot be accurately ascertained, but by an infinity of trials in great buildings; a model cannot be relied on: for a large and a small building, even of the same form, require

different proportions.

in profe was Pherecides Syrus: the first Roman was Appius Cæcus, who composed a declamation against Pyrrhus. The four books of the Chatah Bhade, which is the facred book of Hindostan, are composed in verse stanzas; and the Arabian compositions in prose followed long after those in verse. To account for that fingular fact, many learned pens have been employed; but without fuccels. By some it has been urged, that as memory is the only record of events where writing is unknown, history originally was composed in verse for the fake of memory. This is not fatisfactory. To undertake the painful talk of compoling in verse, merely for the fake of memory, would require more forefight than ever was exerted by a barbarian: not to mention that other means were used for preserving the memory of remarkable events; a heap of stones, a pillar, or other object that catches the eye. The account given by Longinus is more ingenious. In a fragment of his treatife on verse, the only part that remains, he observes, "that measure or verse belongs to poetry; because poetry represents the various passions with their language; for which reason the ancients, in their ordinary discourse, delivered their thoughts in verse

rather than in profe." Longinus thought, that an-

ciently men were more exposed to accidents and dan-

gers, than when they were protected by good govern-

ment and by fortified cities. But he seems not to have

adverted, that fear and grief, inspired by dangers and

misfortunes, are better fuited to humble profe than to

elevated verse. It may be added, that however natu-

ral poetical diction may be when one is animated with

any vivid passion, it is not supposable that the ancients

never wrote nor spoke but when excited by passion.

Their history, their laws, their covenants, were cer-

was of a much later date. The first Greek who wrote

tainly not composed in that tone of mind. An important article in the progress of the fine arts. which writers have not fufficiently attended to, will perhaps explain this mystery. The article is the pro-

From the fine arts mentioned, we proceed to lite-Literary rature. It is agreed, among all antiquaries, that the composifirst writings were in verse, and that writing in prose tion.

fession of a bard, which sprung up in early times before writing was known, and died away gradually See the as writing turned more and more common t

Writing.

The fongs of the bards, being univerfal favourites, + See Bard, were certainly the first compositions that writing was employed upon: they would be carefully collected by the most skilful writers, in order to preserve them in perpetual remembrance. The following part of the progress is obvious. People acquainted with no written compositions, but what were in verse, composed in verse their laws, their religious ceremonics, and every memorable transaction that was intended to be preserved in memory by writing. But when subjects of writing multiplied, and became more and more involved; when people began to reason, to teach, and to harangue; they were obliged to defcend to humble profe: for to confine a writer or speaker to verse in handling subjects of that nature would be a burden unfupportable.

Hiftory.

The profe compositions of early historians are all of them dramatic. A writer destitute of art is naturally prompted to relate facts as he faw them performed: he introduces his perfonages as speaking and conferring; and he himfelf relates what was acted, and not fpoke. The historical books of the Old Testament are composed in that mode; and so addicted to the dramatic are the authors of those books, that they frequently introduce God himfelf into the dialogue. At the fame time, the fimplicity of that mode is happily fuited to the poverty of every language in its early periods. The dramatic mode has a delicious effect in expressing sentiment, and every thing that is simple and tender. Read, as an instance of a low incident becoming, by that means, not a little interesting, Ruth . 8. to iv. 16.

The dramatic mode is far from pleafing so much in relating bare historical facts. Read, as an example, the story of Adonijah in 1 Kings i. 11-49.

In that passage there are frequent repetitions; not however by the same person, but by different persons, who have occasion in the course of the story to say the fame things; which is natural in the dramatic mode, where things are represented precisely as they were transacted. In that view, Homer's repetitions are a beauty, not a blemith; for they are confined to the dramatic part, and never occur in the narrative.

But the dramatic mode of composition, however, pleafing, is tedious and intolerable in a long history. In the progress of society new appetites and new pasfions arife; men come to be involved with each other in various connexions; incidents and events multiply, and history becomes intricate by an endless variety of circumstances. Dialogue accordingly is more sparingly used, and in history plain narration is mixed with it. Narration is as it were the ground-work; and dialogue is raifed upon it, like flowers in embroidery. Homer is admitted by all to be the great mafter in that mode of composition.

The narrative mode came in time fo to prevail, that in a long chain of hiltory, the writer commonly leaves off dialogue altogether. Early writers of that kind appear to have very little judgment in diffinguishing capital facts from minute circumstances, such as can be supplied by the reader without being mentioned. The history of the Trojan war by Dares Phrygius is a cu-

Vol. II. Part I.

rious instance of that cold and creeping manner of composition. The Roman histories before the time of Ciccro are chronicles merely. Cato, Fabius Pictor, and Pifo, confined themselves to naked facts. In the Augustæ Historiæ Scriptores we find nothing but a jejune narrative of facts, commonly of very little moment, concerning a degenerate people, without a fingle incident that can rouse the imagination or exercife the judgment. The monkish histories are all of them composed in the same manner.

The dry narrative manner being very little interesting or agreeable, a taste for embellishment prompted fome writers to be copious and verbole. Saxo-Grammaticus, who in the 12th century composed in Latin a history of Denmark surprisingly pure at that early period, is extremely verbose and full of tautologies. Such a style, at any rate unpleasant, is intolerable in a modern tongue, before it is enriched with a flock of phrases for expressing aprly the great variety of incidents that enter into history.

The perfection of historical composition which writers at last attain to after wandering through various imperfect modes, is a relation of interesting facts, connected with their motives and confequences. A history of that kind is truly a chain of causes and ef-

The history of Thucydides, and still more that of Eloquence.

Tacitus, are shining instances of that mode.

Eloquence was of a later date than the art of literary composition; for till the latter was improved there were no models for fludying the former. Cicero's oration for Roseius is composed in a style diffuse and highly ornamented; which, fays Plutarch, was univerfally approved, because at that time the style in Afia, introduced into Rome with its luxury, was in high vogue. But Cicero, in a journey to Greece, where he leifurely fludied Greek authors, was taught to prune off superfluities, and to purify his style, which he did to a high degree of refinement. He introduced into his native tongue a sweetness, a grace, a majefly, that furprifed the world, and even the Romans themselves. Cicero observes with great regret, that if ambition for power had not drawn Julius Casfar from the bar to command legions, he would have become the most complete orator in the world. So partial are men to the profession in which they excel. Eloquence triumphs in a popular affembly; makes fome figure in a court of law composed of many judges, very little where there is but a fingle judge, and none at all it a despotic government. Eloquence flourished in the republics of Athens and of Rome; and makes fome figure at prefent in a British House of Commons.

The Greek stage has been justly admired among all Tregedy, polite nations. The tragedies of Sophocles and Euripides in particular are by all critics held to be perfect in their kind, excellent models for imitation, but far above rivalship. If the Greek stage was so early brought to maturity, it is a phenomenon not a little fingular in the progress of arts. The Greek tragedy made a rapid progress from Thespis to Sophocles and Euripides, whose compositions are wonderful productions of genius, confidering that the Greeks at that period were but beginning to emerge from roughness and barbarity into a taste for literature. The compofitions of Eschylus, Sophoeles, and Euripides, must

have been highly relished among a people who had no idea of any thing more perfect. We judge by comparison, and every work is held to be perfect that has no rival. It ought at the same time to be kept in view, that it was not the dialogue which chiefly enchanted the Athenians, nor variety in the passions represented, nor persection in the actors; but machinery and pompous decoration, joined with exquisite music. That these particulars were carried to the greatest height, we may with certainty conclude from the extravagant fums bestowed on them: the exhibiting a fingle tragedy was more expensive to the Athenians than their fleet or their armies in any fingle campaign.

One would imagine, however, that these compositions were too simple to enchant for ever: as variety in action, sentiment, and passion, is requisite, without which the stage will not continue long a favourite entertainment: and yet we find not a fingle improvement attempted after the days of Sophocles and Euripides. The manner of performance, indeed, prevented absolutely any improvement. A fluctuation of passion and refined fentiments would have made no figure on the Grecian stage. Imagine the discording scene between Brutus and Cassius in Julius Cæsar to be there exhibited, or the handkerchief in the Moor of Venice: how flight would be their effect, when pronounced in a mask, and through a pipe? The workings of nature upon the countenance, and the flexions of voice expreflive of various feelings, so deeply affecting in modern representation, would have been entirely lost. If a great genius had arisen with talents for composing a pathetic tragedy in perfection, he would have made no figure in Greece. An edifice must have been erected of a moderate fize: new actors must have been trained to act with a bare face, and to pronounce in their own voice. And after all, there remained a greater miracle still to be performed, viz. a total reformation of taste in the people of Athens. In one word, the simplicity of the Greek tragedy was fuited to the manner of acting; and that manner excluded all improvements.

With respect to comedy, it does not appear that the Greek comedy surpassed the tragedy in its progress toward perfection. Horace mentions three stages of Greek comedy. The first well suited to the rough and coarse manners of the Greeks, when Eupolis, Cratinus, and Aristophanes, wrote. These authors were not ashamed to represent on the stage real persons, not even difguifing their names; of which we have a striking instance in a comedy of Aristophanes, called The Clouds, where Socrates is introduced, and most contemptuously treated. This fort of comedy, sparing neither gods nor men, was reftrained by the magistrates or. Athens, fo far as to prohibit persons to be named on the stage. This led writers to do what is done at prefent: the characters and manners of known persons were painted so much to the life, that there could be no miltake; and the fatire was indeed heightened by this regulation, as it was an additional pleafure to find out the names that were meant in the representation. This was termed the middle comedy. But as there still remained soo great scope for obloquy and licentiousness, a law was made, prohibiting real events or incidents to be introduced upon the stage. This law happily banished satire against individuals, and confined it to manners and sustoms in general. Obedient to this law are

the comedies of Menander, Philemon, and Diphilus. who flourished about 300 years before the Christian era. And this is termed the third stage of Greek comedy. The comedies of Aristophanes which still remain, err not less against taste than against decency. But the Greek comedy is supposed to have been considerably refined by Menander and his cotemporaries. Their works, however, were far from perfection, if we can draw any conjecture from their imitator Plautus, who wrote about a century latter. Plautus was a writer of genius; and it may be reasonably supposed that his copies did not fall much short of the originals, at least in matters that can be faithfully copied; and he shows very little art, either in his compositions or in the conduct of his pieces. With respect to the former, his plots are wondrous fimple, very little varied, and very little interesting. The subject of almost every piece is a young man in love with a music girl, defiring to purchase her from the procurer, and employing a favourite slave to cheat his father out of the price; and the different ways of accomplishing the cheat is all the variety we find. In some few of his comedies the story rifes to a higher tone, the music girl being discovered to be the daughter of a freeman, which removes every obstruction to a marriage between her and her lover. In the conduct of his pieces there is a miserable defect of art. Instead of unfolding the subject in the progress of the action, as is done by Terence, and by every modern writer, Plautus introduces a person for no other end but to explain the story to the audience. In one of his comedies, a household god is so obliging as not only to unfold the subject, but to relate beforehand every particular that is to be represented, not excepting the catastrophe.

The Roman theatre, from the time of Plautus to that of Terence, made a rapid progress. Aristotle defines comedy to be " an imitation of light and trivial subjects, provoking laughter." The comedies of Plautus correspond accurately to that definition: those

of Terence rife to a higher tone.

Nothing is more evident than the superiority of Terence above Plautus in the art of writing; and, confidering that Terence is a later writer, nothing would. appear more natural, if they did not copy the same originals. It may be owing to genius that Terence excelled in purity of language and propriety of dialogue; but how account for his superiority over Plantus in the construction and conduct of a play.? It will not certainly be thought, that Plautus would imitate the worstconstructed plays, leaving the best to those who should come after him. This difficulty does not feem to have occurred to any of the commentators. Had the works of Menander and of his cotemporaries been preserved, they probably would have explained the mystery; which for want of that light will probably remain a mystery for ever.

Homer has for more than 2000 years been held the Epopee. prince of poets. Such perfection in an author who flourished when arts were far short of maturity, is truly wonderful. The nations engaged in the Trojan war are described by him as in a progress from the shepherd state to that of agriculture. Frequent mention is made. in the Iliad of the most eminent men being shepherds. Andromache, in particular, mentions seven of her brethren who were sain by Achilles as they tended their

father's flocks and herds. In that state, garments of woollen cloth were used; but the skins of beats, the original clothing, were fill worn as an upper garment; every chief in the Iliad appears in that drefs. Such indeed was the simplicity of this early period, that a black ewe was promifed by each chief to the man who would undertake to be a fpy. In times of such simplicity, literature could not be far advanced; and it is a great doubt, whether there was at that time a fingle poem of the epic kind for Homer to imitate or improve upon. Homer is undoubtedly a wonderful genius, perhaps the greatest that ever existed: his fire, and the boldness of his conceptions, are inimitable. But in that early age, it would fall little short of a real miracle, to find such ripenels of judgment, and correctness of execution, as in modern writers are the fruits of long experience and progressive improvements during the course of many centuries. Accordingly, that Homer is far from heing so ripe, or so correct, cannot escape the observation of any reader of taste and discernment. One striking particular is, his digressions without end, which draw our attention from the principal subject. Diomedes, for instance, meeting with Glaucus in the field of battle, and doubting from his majestic air, whether he might not be an immortal, inquires who he was, declaring that he would not fight with a god. Glaucus lays hold of this very flight opportunity, in the very heat of action, to give a long history of his family. In the mean time, the reader's patience is put to a trial, and his ardour cools. Again, Agamemnon defiring advice how to refift the Trojans, Diomedes springs forward; but before he offers advice, gives the history of all his progenitors, and of their characters, in a long train. And, after all, what was the fage advice that required such a preface? It was, that Agamemnon should exhort the Greeks to fight bravely. At any rate, was Diomedes fo little known, as to make it proper to suspend the action at so critical a juncture, for a genealogical history? There is a third particular which justly merits censure; and that is, an endless number of minute circumstances, especially in the description of battles, where they are most improper. The capital beauty of an epic poem is, the felection of fuch incidents and excumitances as make a deep impression, keeping out of view every thing low or familiar. An account of a fingle battle employs the whole fifth book of the Iliad and a great part of the fixth: yet in the whole there is no general action; but unknown warriors, whom we never heard of before, killed at a diftance with an arrow or a javelin; and every wound described with anatomical accuracy. The whole feventeenth book is employed in the contest about the dead body of Patroclus, stuffed with minute circumstances, below the dignity of an epic poem. In such seenes the reader is fatigued with endless particulars; and has nothing to support him but the melody of Homer's verification. Having traced the progress of the fine arts toward

the decline maturity, in a fummary way, the decline of these arts of the fine comes next in order. An art, in its progress toward maturity, is greatly promoted by emulation; and, after arriving at maturity, its downfal is not less promoted by it. It is difficult to judge of perfection but by comparison; and an artist, ambitious to outstrip his

predecessors, cannot submit to be an imitator, but must

firike out fomething new, which, in an art advanced to ripenels, feldom fails to be a degeneracy. This cause of the decline of the fine arts may be illustrated by various inflances. The perfection of vocal mulic is to accompany paffion, and to enforce fentiment. In ancient Greece, the province of mulic was well underflood; which being confined within its proper fphere, had an enchanting influence. Harmony at that time was very little cultivated, because it was of very little use: melody reaches the heart, and it is by it chiefly that a fentiment is enforced, or a passion soothed; harmony, on the contrary, reaches the ear only; and it is a matter of undoubted experience, that the most melodious airs admit but of very fimple harmony. Artifts, in later times, ignorant why harmony was fo little regarded by the ancients, applied themselves seriously to its cultivation; and they have been wonderfully fuccefsful. But they have been fuccefsful at the expence of melody; which in modern compositions, generally speaking, is lost amid the blaze of harmony. These compositions tickle the ear by the luxury of complicated founds, but feldom make any impression on the heart. The Italian opera, in its form, resembles the Greek tragedy, from which it is evidently copied; but very little in substance. In the latter, music being made fubservient to fentiment, the dialogue is nervous and fublime: in the former, the whole weight is laid on music; and the dialogue, devoid of sentiment, is weak and spiritless. Restless man knows no golden mean, but will be attempting innovations without end .- By the fame ambition, architecture has visibly declined from its perfection. The Ionic was the favourite order when architecture was in its height of glory. The Corinthian order came next; which, in attempting greater perfection, has deviated from the true fimplicity of nature: and the deviation is still greater in the Composite order. With respect to literary productions, the first essays of the Romans were very imperfect. We may judge of this from Plautus, whose compositions are abundantly rude, though much admired by his cotemporaries, being the best that existed at that time. The exalted spirit of the Romans hurried them on to the grand and beautiful; and literary productions of all kinds were in perfection when Augustus reigned. In attempting still greater perfection, the Roman compositions became a strange jumble of inconfiftent parts: they were tumid and pompous; and, at the same time, full of antitheses, conceit, and tinsel wit. Every thing new in the fine arts pleases, though less perfect than what we are accustomed to; and, for that reason, such compositions were generally relished. We see not by what gradual steps writers, after the time of Augustus, deviated from the patterns that were before them; for no book of any moment after that time is preferred till we come down to Seneca, in whose works nature and simplicity give place to artificial thought and bastard wit. He was a great corrupter of the Roman tafte; and after him nothing was relished but brilliant strokes of funcy, with very little regard to fentiment: even Virgil and Cicero made no figure in comparison. Lucan has a forced elevation of thought and flyle very difficult to be fupported; and, accordingly, he finks often into puerile reflections; witness his encomium on the river Po; which, fays he, would equal the Danube, had it the

10 Causes of Air.

fame number of tributary streams. Quintilian, a writer of true and classical taste, who was protected and encouraged by Velpasian, attempted to stem the tide of false writing. His rhetoric is composed in an ele-gant style; and his observations contain every delicacy of the critical art. At the same time flourished Tacitus, possessing a more extensive knowledge of the nature of man than any other author, ancient or modern, if Shakespeare be not excepted. His style is original, concife, compact, and comprehensive; and, in what is properly called his biffory, perfectly correct and beautiful. He has been imitated by several, but never equalled by any. Brutus is faid to be the last of the Romans for love of liberty: Quintilian and Tacitus may be faid to be the last of the Romans for literary genius. Pliny the younger is no exception; his flyle is affected, turgid, and full of childish brilliancy. Seneca and Pliny are proper examples of writers who fludy show more than substance, and who make sense yield to found. The difference between these authors and those of the Augustan age, resembles the difference between Greek and Italian music. Music, among the Greeks, limited itself to the employment to which it is destined by nature, viz. to be the handmaid of sense, to enforce, enliven, or sweeten a sentiment. In the Italian opera, the mistress is degraded to be handmaid; and harmony triumphs, with very little regard to fentiment.

Another great cause that precipitates the downsal of every fine art is despotism. The reason is obvious; and there is a difmal example of it in Rome, particularly with regard to eloquence. We learn from a dialogue accounting for the corruption of the Roman eloquence, that in the decline of the art it became fashionable to stuff harangues with impertinent poetical quotations, without any view but ornament merely; and this also was long fashionable in France. It happened unluckily for the Romans, and for the world, that the fine arts were at their height in Rome, and not much upon the decline in Greece, when despotism put an end to the republic. Augustus, it is true, retarded their fall, particularly that of literature; it being the politic of his reign to hide despotism, and to give his government an air of freedom. His court was a school of urbanity, where people of genius acquired that delicacy of tatle, that elevation of fentiment, and that purity of expression, which characterize the writers of his time. He honoured men of learning, admitted them to his table, and was bountiful to them. It would be painful to follow the decline of the fine arts in Rome to their total extirpation. The tyranny of Tiberius, and of subsequent emperors, broke at lait the elevated and independent spirit of the brave Romans, reduced them to abject flavery, and left not a spark of genius. The fcience of law is the only exception, as it flourished even in the worst of times: the Roman lawyers were a respectable body, and less the object of jealousy than men of power and extensive landed property. Among the Greeks also, a conquered people, the fine arts decayed; but not fo rapidly as at Rome; the Greeks, farther removed from the leat of government, being less within the reach of a Roman tyrant. During their depression, they were guilty of the most puerile conceits: witness verses composed in the form of an axe, an egg, wings, and fuch like. The flyle of Greek

authors, in the reign of the emperor Adrian, is unequal, obscure, stiff, and affected. Lucian is the only exception that may be made.

, We need fearce any other cause but despotism, to account for the decline of statuary and painting in Greece. These arts had arrived at their utmost perfection about the time of Alexander the Great; and from that time they declined gradually with the vigour of a free people; for Greece was now enflaved by the Macedonian power. It may in general be observed, that when a nation becomes flationary in that degree of power which it acquires from its conftitution and fituation, the national spirit subsides, and men of talents become rare. It is still worse with a nation that is funk below its former power and pre-eminence; and worst of all when it is reduced to slavery. Other causes concurred to accelerate the downfal of the arts mentioned. Greece, in the days of Alexander, was filled with statues of excellent workmanship; and there being little demand for more, the later statuaries were reduced to heads and busts. At last the Romans put a total end both to statuary and painting in Greece, by plundering it of its finest pieces; and the Greeks, exposed to the avarice of the conquerors, bestowed no

longer any money on the fine arts.

The decline of the fine arts in Rome is by a writer Petronius

of tafte and elegance ascribed to a cause different from Arbiter any above mentioned, a cause that overwhelms manhood as well as the fine arts wherever it prevails; and that is opulence, joined with its faithful attendants avarice and luxury. " In ancient times (fays he), when naked virtue had her admirers, the liberal arts were in their highest vigour; and there was a generous contest among men, that nothing of real and permanent advantage should long remain undiscovered. Democritus extracted the juice of every herb and plant; and, left the virtue of a fingle stone or twig should escape him, he consumed a lifetime in experiments. Eudoxus, immerfed in the study of astronomy, spent his age upon the top of a mountain. Chrysippus, to stimulate his inventive faculty, thrice purified his genius with hellebore. To turn to the imitative arts: Lyfippus, while labouring on the forms of a fingle flatue, perished from want. Myron, whose powerful hand gave to the brafs almost the foul of man and animals,-at his death found not an heir! Of us of modern times what shall we say? Immersed in drunkenness and debauchery, we want the spirit to cultivate those arts which we possess. We inveigh against the manners of antiquity; we fludy vice alone; and vice is all we teach. Where now is the art of reasoning? Where astronomy? Where is the right path of wifdom? What man now-a-days is heard in our temples to make a vow for the attainment of eloquence, or for the discovery of the fountain of true philosophy? Nor do we even pray for health of body, or a found under-flanding. One, while he has scarce entered the porch of the temple, devotes a gift in the event of the death of a rich relation; another prays for the discovery of a treasure; a third for a ministerial fortune. The senate itself, the exemplary preceptor of what is good and laudable, has promifed a thouland pounds of gold to the capitol; and, to remove all reproach from the crime of avarice, has offered a bribe to Jupiter himself. How should we wonder that the art of painting has declined,

when, in the eyes both of the gods and men, there is more beauty in a mass of gold than in all the works of Phidias and Apelles."-In England, the fine arts are far from such perfection as to suffer by opulance. They are in a progress, it is true, toward maturity; but

they proceed in a very flow pace.

There is still another cause that never fails to undermine a fine art in a country where it is brought to perfection, abstracting from every one of the causes above mentioned. It is remarked a little above: that nothing is more fatal to an art or to a science than a performance fo much superior to all of the kind as to extinguish emulation. This remark is exemplified in the great Newton, who having furpassed all the ancients, has not left to his countrymen even the faintest hope of rivalling him; and to that cause is attributed the visible decline of mathematics in Great Britain. The same cause would have been fatal to the arts of flatuary and painting among the Greeks, even though they had continued a free people. The decay of painting in modern Italy is, probably, owing to the same cause: Michael Angelo, Raphael, Titian, &c. are lofty oaks that bear down young plants in their neighbourhood and intercept from them the funshine of emulation. Had the art of painting made a flower progress in Italy, it might have there continued in vigour to this day. Velleius Paterculus fays judiciously, "Ut primo ad confequendos quos priores ducimus accendimur; ita, ubi aut præteriri aut æquari eos posse desperavimus, studium cum spe senescit; et quod adsequi non poteft, sequi definit : præteritoque eo in quo eminere non possimus, aliquid in quo nitumur conqui-

The decline of an art or science proceeding from the foregoing cause, is the most rapid where a strict comparison can be instituted between the works of different masters. The superiority of Newton above every other mathematician can be afcertained with precision; and hence the fudden decline of that science in Great Britain. In Italy a talent for painting continued many years in vigour, because no painter appeared with fuch fuperiority of genius as to carry perfection in every branch of the art. As one surpassed in designing, one is colouring, one in graceful attitudes, there was still scope for emulation. But when at last there was not a fingle perfection but what one or other mafter had excelled in, from that period the art began to languish. Architecture continued longer in vigour than painting, because the principles of comparison in the former are less precise than in the latter. The artist who could not rival his predecessors in an established mode, fought out a new mode for himself, which, though perhaps less elegant or perfect, was for a time

Ufeful arts supported by novelty.

Useful arts will never be neglected in a country less subject so decline, where there is any police; for every man finds his account in them. Fine arts are more precarious. They are not relished but by persons of taste, who are rare; and such as can spare great sums for support-ing them are still more rare. For that reason, they will never flourish in any country, unless patronized by the fovereign, or by men of power and opulence. They merit such patronage, as one of the springs of government: and a capital spring they make, by multiplying amusements, and humanizing manners; upon

which account they have always been encouraged by Arm good princes.

General Theory of the Polite ARTS. The effence of Tobory the polite arts, as before observed, consists in expression. of the po-The end of all these arts is pleasure; whereas the end lite arts. of the sciences is instruction and utility. Some of the polite arts indeed, as eloquence, poetry, and architecture, are frequently applied to objects that are ufcful, or exercifed in matters that are instructive, as we shall show more particularly in their proper place; but in these cases, though the ground-work belongs to those sciences which employ the understanding, yet the expression arises from the inventive faculty. It is a picture that is defigned by Minerva, to which the Mufes add the colouring, and the Graces the frame. This union forms therefore the perfection of the art, according to that fententious and well known precept of Horace: Omne tulit punaum, qui miscuit utile dulci.

Under the denomination therefore, of Polite Arts, What site we comprehend, 1. Eloquence; 2. Poetry; 3. Music; so denome, 4. Painting; 5. Sculpture; 6. Graving; 7. Architecture; 8. Declaration; 9. Dancing. Particular deformation of the first section of the secti scriptions of these arts are given under their respective names. This branch of the present article is intended as a general introduction to them; and, as fuch, will

be occasionally referred to.

There is one very effential reflection, which it appears to us proper to make in the first place, on the polite arts in general. All the rules in the world are not fufficient to make a great poet, an able orator, or an excellent artift; because the quality, necessary to form thefe, depends on the natural disposition, the fire of genius, which no human art can confer, but which is the pure gift of heaven. The rules, however will prevent a man from being a bad artift, a dull orator, or Use of prea wretched poet; feeing they are the reflections of the cepts. greatest masters in those arts, and that they point out the rocks which the artift should shun in the exercise of his talents. They are of use moreover, in facilitating his labours, and in directing him to arrive by the shortest and surest road at perfection. They refine, ftrengthen and confirm, his tafte. Nature, abandoned to herfelf, has fomething conftantly wild and favage. Art, founded on just and fagacious rules, gives her elegance, dignity and politeness; and it is impossible to facrifice properly to the Graces, without knowing the incense that is pleasing to them.

e incense that is pleasing to them.

Beauty, reBeauty is the object of all the polite arts. It is not mus, tofte, however, fo eafy, as it may feem, to give a clear and what. determinate idea of what we precifely mean by that term*. Many able writers, who have treated ex- * See the pressly on the subject, have shown that they were to-article tally ignorant of what it was. It is one of these express-Beauty. fions that we comprehend immediately, that present us with a clear and precise idea, that leave a distinct impression on our minds, when it is simply written or pronounced; but which philosophers envelope in darkneis, when they attempt to elucidate it by definitions and descriptions; and the more, as mankind have different ideas of beauty, their opinions and taftes being as various as their understandings and physiognomics. We may fay, however, in general, that beauty refults from the various perfections of which any object is fufceptible, and which it actually possesses; and that the perfections which produce beauty confift principally in.

the agreeable and delightful proportions which are found, 1. Between the feveral parts of the same object; 2: Between each part and the whole together; 3. Between the parts and the end or defign of the object to which they belong. Genius, or invention, is that faculty of the mind by which beauty is produced. + See Taffe. Taffe +, disposition, or rather the natural sensation of the mind refined by art, ferves to guide the genius in discerning, embracing, and producing, that which is beautiful of every kind. From whence it follows, that the general theory of the polite arts is nothing more than the knowledge of what they contain that is truly beautiful and agreeable; and it is this knowledge,

this theory, which modern philosophers call by the Latin name of asthetica.

It should be constantly remembered, that the essence of the polite arts confifts in expression. This expression lies fometimes in the words, and fometimes in the pen; fometimes in founds and their harmony, and at others in corporeal attitudes; fometimes in the pencil or in the chifel, and at others in the graver; fometimes in a proper disposition or judicious employment of the mechanic arts, and at others merely in their manner of acting. From whence arise those arts that we have mentioned, and which are described in

16 their order. First gene-

ral rule.

Novelty

Invention.

The general theory of the polite arts, or esthetics, necessarily supposes, therefore, certain rules; but these general rules are of no great number. The first is, That whoever would devote himself to the polite arts, should above all things confult his genius; divest him-felf of self-love; and examine if he be a true son of Apollo, and cherished by the Muses: for

In vain, rash author, dost thou strive to climb, By lofty verse, Parnassus' height sublime, If heaven does not by fecret powers inspire, Or if thy natal star darts not poetic fire.

Imagination, This precept with regard to poetry in particular, is applicable to all the polite arts in general; for their most happy success is founded on imagination. By this term we understand, in general, a faculty of the mind, a particular genius, a lively invention, a certain fubtle spirit, which gives a facility in discovering fomething new. But it is necessary also to prescribe just bounds to this term new, which must not be here taken in an absolute sense. Solomon wisely remarks, that, even in his time, there was nothing new under the fun. In fact, all that exists, and all that is capable of being discovered in the known world, has already been discovered. The fine arts in their imitations of nature, in their expressions, can borrow images, figures, comparisons, from those things only that exist and are known. As there have been from the beginning of the world to our days, millions of authors in each of the polite arts, almost all the possible combinations of the various subjects have been produced by their lively imaginations; and when we hear the ignorant part of mankind talk of a work of wit or of art that is entirely new, that offers ideas which were before utterly unknown, that had never entered into the brain of any other man, we should refer such affertions to the class of popular errors; and reflect on those stories we every day hear of certain empiries, who pretend to be alone possessed of marvellous methods of cure by means of simples; as if there were any plant, any stalk

of grafs that grows in our world, that can have escaped the refearches of botanists. But the novelty, of which we here speak, consists in the ingenious use of combinations of all the various objects of nature, that are new, happy, and agreeable, that have not yet been exhausted, and which appear even to be inexhaustible; and of the use which the artist makes of all new discoveries, which he turns to his advantage, by a judicious application. Invention therefore supposes a considerable fund of preliminary knowledge, fuch as is capable of furnishing ideas and images, to form new combinations. But there is no art by which invention itself can be produced; for that, as we have already faid, is the gift of heaven; and it is an endowment which we cannot even make use of whenever we please. We would rather fay, therefore, that invention confilts in producing, in works of genius, that which is unexpected; an object, a harmony, a perfection, a thought, an expression of which we had no idea, that we could not foresce, nor hope to find, where the artist has so happily placed it, and where we perceive it with delight. This idea appears applicable to fuch of the polite arts as affect the mind by the hearing as well as by the fight; and it is a matter that is highly effential.

The fecond rule is, That every artift ought incef-2d Rule, fantly to labour in the improvement of his tafte; in Improveacquiring that sensible, refined, and clear discernment, taste. by which he will be enabled to distinguish the real beauties in each object, the ornaments that are agreeable to it, and the proportions and relations that subfift among the several parts: and by this faculty, he will be regulated in the employment of his natural talents. This labour confitts not only in the profound reflections he will make on the properties of objects as they relate to the fine arts, but also in a constant, assiduous

study of the grand models of beauty.

The third rule to be observed in the practice of the 3d Imitapolite arts, is the imitation of nature. Every object in tion of nathe universe has its peculiar nature, of which the artist ture. should never lose fight in his manner of treating it. In vain will he otherwise ornament his work with the most refined and most brilliant strokes; for, if nature be not justly imitated, it will for ever remain imperfect. The fublime Homer has fometimes finned against this rule: for, as the gods have a nature peculiar to themselves, it cannot be a just imitation when we attribute to them passions that are scarce pardonable in mortals, and make them frequently converse in a language that is at once vulgar and ridiculous. It was not to imitate nature, to put in the mouth of a hero, at the moment of a decifive battle, an harangue that must become tedious by its excessive length, and which certainly could not have been heard by the thousandth part of a numerous army: but we have already touched upon some of the faults that are strewed over the poems of that great man; to multiply or dwell upon them would be ungrateful. We must, however, observe that this imitation of nature, which appears at first view to simple and so eafy, is of all things the most difficult in practice; and that it requires a difcernment fo fagacious, and an expression so happy, as is rarely bestowed by heaven on mortal man.

Perspicuity forms the fourth rule of expression. In 4th, Perall the fine arts, in general, an obscure, perplexed, am-spicuity, biguous, and claborate expression, is always bad. The

Art Artaba.

true striking beauty must be manifest and perceptible to the most ignorant of mankind as well as the most learned. Those are ever false or inferior beauties that have occasion for a covering, a kind of veil that may make them appear greater than they really are: true beauty wants no veil, but shines by its native lustre. From the union of the true imitation of nature with perspicuity of expression arises that truth which is so essential in the productions of the fine arts.

23 5th, Elevatiments.

In all the polite arts, and in all the subjects they tion of fen- embrace, there must necessarily reign an elevation of fentiment, that expresses each object in the greatest perfection of which it is susceptible; that imitates nature in her most exalted beauty. This makes the fifth general rule. The defign of the fine arts being to excite pleasure by the expression of that which is beautiful, every artist should raise himself above his subject; and, choosing the most favourable light wherein to place it, should there embellish it with the greatest, most noble, and beautiful ornaments, that his own genius can suggest; still, however, observing a strict imitation of nature.

23 6th, The Cublime to be endeavoured after.

• See the article

GRAN-

DEUR and

Sublimity.

From the observation of these two last rules results the *[ublime*, which is the union of the greatest perspicuity with the strictest truth and most exalted elevation possible. It is necessary to remark here, that the most fimple and common subjects are susceptible of a sublime that is agreeable to their nature. An idyl or landscape may be as sublime in their kinds as an epic poem or a history piece. When Moses begins the book of Genefis with these words, In the beginning God created the beaven and the earth; or when he tells us, that God faid, Let there be light, and there was light; these expressions are sublime in the highest degree, because they are perfectly clear, true, and elevated. Every author should therefore endeavour after the sublime * in every subject that he undertakes; and this makes the fixth and last general rule in the practice of the polite arts. But if he cannot attain to this, it is, however, indifpenfably necessary that he constantly make use of expressions that are noble and refined. Every thing that is low, indecent, or disigreeable, is naturally repugnant to the sublime, and ought to be for ever banished from all works that proceed from the noble and liberal

ART is also an appellation given to several superstitious practices, as, St Anfelbm's art, St Paul's art,

Art and Part, in Scots law. See Accessory.

ARTA, by some called Larta, a town of Lower Albania, in Turkey in Europe, with a Greek archbishop's see. It is a pretty large town, and contains about 7000 or 8000 inhabitants, Greeks and Turks; but the former are the most numerous. The cathedral has as many windows and doors as there are days in the year. It is supported by above 2000 marble pillars; and was built by Michael Ducas Commeno emperor of Constantinople, as appears by an inscription over the great door. It carries on a confiderable trade, particularly in tobacco and furs. E. Long. 31. 30. N. Lat. 39. 28.

ARTABA, an ancient measure of capacity used by the Persians, Medes, and Egyptians.

The Persians artaba is represented by Herodotus as bigger than the Attic medimnus by three Attic chenixes: from which it appears that it was equal to 62 Artabanus Roman modii; consequently that it contained 1663 pounds of wine or water, or 1267 pounds of wheat. Artemido-The Egyptian artaba contained five Roman modii, and fell short of the Attic medimnus by one modius; confequently held 1337 pounds of water or wine, 100 pounds of wheat, or 60 of flour.

ARTABANUS, the name of feveral kings of Parthia. See PARTHIA.

ARTABAZUS, the fon of Pharnaces, commanded the Parthians and Chorasmians in the samous expedition of Xerxes. After the battle of Salamis, he escorted the king his master to the Hellespont with 60,000 chosen men; and after the battle of Platza, in which Mardonius engaged contrary to his advice, he made a noble retreat, and returned to Asia with 40,000 men under his command.

ARTAXATA, orum, the royal refidence and metropolis of Armenia Major (Strabo, Pliny, Juvenal), and built according to a plan of Hannibal, for King Artaxias, after whom it was called. It was fituated on an elbow of the river Araxes, which formed a kind of peninfula, and furrounded the town like a wall, except on the fide of the ifthmus, but this fide was fecured by a rampart and ditch. This town was deemed for strong, that Lucullus, after having defeated Tigranes, durst not lay siege to it; but Pompey compelled him to deliver it up without striking a blow. It was then levelled with the ground; but the Armenians have a tradition, that the ruins of it are still to be seen at a place called Ardachat. Sir John Chardin fays, that it has the name of Ardachat from Artaxias, whom in the East they call Ardechier. Here are the remains of a flately palace which the Armenians take to be that of Tiridates who reigned in the time of Constantine the Great. One front of this building is but half ruined, and there are many other fine antiquities which the inhabitants call Tad. Tradat, that is, the throne of Tiridates. Tavernier also mentions the ruins of Artaxata between Erivan and Mount Ararat, but does not specify them. The ancient geographers mention another city of the same name, likewise situated on the Araxes, but in the northern part of Media, known among the ancients by the name of Acropatia.

ARTAXERXES, the name of feveral kings of Persia. See Persia.

ARTEDIA: A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 45th order, Umbellate. The involucra are pinnatifid; the floscules of the disc are masculine; and the fruit is hispid with scales.—There is but one species, the squamata, with squamose seeds, a native of the East: Rewvolf found it growing on Mount Libanus. It is an annual plant, whose stalks rife about two feet high, sending out a few fide-branches, which are garnished with narrow compound leaves resembling those of dill; the extremity of the stalk is terminated by a large umbel of white flowers, composed of five unequal petals. These are succeeded by roundish compressed fruit, each having two feeds, whose borders are scaly.

ARTEMIDORUS, famous for his Treatife on Dreams. He was born at Ephefus, but took upon him the furname of Daldianus in this book, by way of respect to his mother country Daltis. He styled him-

Artsmille. felf the Ephefian in his other performances. He not only bought up all that had been written concerning the explication of dreams, which amounted to many volumes; but he likewise spent many years in travelling, in order to contract an acquaintance with fortunetellers; he also carried on an extensive correspondence with all the people of this fort in the cities and affemblies of Greece, Italy, and the most populous islands; collecting at the same time all the old dreams, and the events which are faid to have followed them. The work which he wrote on dreams confifted of five books: the first three were dedicated to one Cassius Maximus; and the last two to his son, whom he took a good deal of pains to instruct in the nature and interpretation of dreams. This work, though filled with frivolous observations, contains some things that are interesting. It was first printed in Greek at Venice in 1518; and Rigaltius published an edition at Paris, in Greek and Latin, in 1603, and added some notes. Artemidorus wrote also a treatise upon Auguries, and another upon Chiromancy; but they are not extant. He lived under the emperor Antoninus Pins.

> ARTEMISIA, wife of Mansolus, king of Caria, has immortalized herfelf by the honours which she paid to the memory of her husband. She built for him in Halicarnassus a very magnificent tomb, called the Maufoleum, which was one of the feven wonders of the world, and from which the title of Maufoleum was afterwards given to all tombs remarkable for their grandeur; but the died of regret and forrow before the Maufoleum was finished. She appointed panegyrics to be made in honour of him, and proposed a prize of great value for the person who should compose the best. He died about the end of the 106th Olympiad, 351 years before the Christian era.

ARTEMISIA, queen of Caria, and the daughter of Ligdamis, marched in person in the expedition of Xerxes against the Greeks, and performed wonders in the sca-fight near Salamis, 480 years before the Christian era. Being purfued by an Athenian vessel, she attacked one of the Perlian ships, commanded by Demanthymus, king of Calyndus, her enemy, and funk it; on which the Athenians, thinking that her ship was on the fide of the Greeks, ceafed their pursuit: but Xerxes was the principal person imposed upon in this affair; for believing the had funk an Athenian veffel, he declared, that "the men had behaved like women, and the women like men." Xerxes intrusted her with the care of the young princes of Persia, his fons, when, agreeably to her advice, he abandoned Greece, in order to return to Afia. Thefe great qualities did not fecure her from the weakness of love; the was passionately fond of a man of Abydos, whose name was Durdanus, and was fo enraged at his neglect of her, that she put out his eyes while he was asleep. The gods in order to punish her for this, inspired her with a still stronger passion for him; so that the oracle having advited her to go to Leucas, which was the usage of desperate lovers, she took the leap from thence, and was interred at that place. Many writers confound this Artemina with the former, the wife of Maufolus.

ARTEMISIA, Mugewort, Southernwood, and Wormswood; A genus of the polygamia superflua order, belonging to the syngenesia class of plants; and in the

natural method ranking under the 49th order, Compo- Artemilia. fite-nucamentacea. The receptacle is either naked or a little downy; it has no pappus; the calyx is imbricated with roundish scales; and the corolla has no radii .- The

R

Species are 23; of which the most noted are the following: 1. The vulgaris, or common mugwort, grows naturally on banks and by the fides of foot paths in many parts of Britain; so is seldom admitted into gardens, where it would prove a troublesome weed, as it spreads very fast by its creeping roots. It slowers in June, at which time the plant is ready for use. 2. The dracunculus, or tarragon, which is frequently used in fallads; especially by the French, is a very hardy plant, and spreads greatly by its creeping roots. 3. The abrotanum, or fouthernwood, which is kept in gardens for the fake of its agreeable fcent, is a low shrub, seldom rifing more than three or four feet high, fending out lateral shrubby branches, growing erect, garnished with five briftly leaves, having an agreeable fcent when bruifed: the flowers are produced in spikes from the extremity of the branches; but unless the autumn proves warm, they feldom open in England. 4. The fantonicum produces the femen fantonicum, which is much used for worms in children. It grows naturally in Perlia, from whence the feeds are brought to Europe. It hath the appearance of our wild mugwort; the branches are slender, erect, and garnished with linear winged leaves, and terminated by recurved flender spikes of flowers which have naked receptacles. 5. The artemino maritima, or fea wormwood, grows naturally on the fea coasts in most parts of Britain, where there are several varieties, if not diffind species, to be found. These are low under shrubs, most of which creep at the root, by-which they multiply greatly in their natural fituation, but when transplanted into gardens feldom thrive fo well. 6. The pontica, or pontic wormwood, commonly called Roman wormwood, is a low herbaceous plant, whose stalks die in autumn, and new ones appear in the fpring. These are garnished with finely divided leaves, whose under sides are woolly; and the upper parts of the stalks are furnished with globular flowers which nod on one fide, having naked receptacles. These appear in August, but are rarely succeeded by seeds in Britain. 7. The absinthium, or common wormwood, grows naturally in lanes and uncultivated places, and is too well known to require any particular description. 8. The arborescens, or tree wormwood, grows naturally in Italy and the Levant, near the fea. It rifes, with a woody stalk, fix or seven feet high, sending out many ligneous branches garnished with leaves somewhat like those of the common wormwood, but more finely divided, and much whiter. The branches are terminated by spikes of globular flowers in autumn, which are feldom fucceeded by feeds in this country.

Culture. The fouthernwood is propagated by flips or cuttings planted in a thady border about the beginuing of April, observing to water them duly in dry weather. In this border they may remain till the following autumn, when they should be transplanted, either into pots or those parts of the garden where they are to remain. The fantonicum is likewife propagated by slips; but the plants should be placed in a dry soil and sheltered situation, where they will endure the cold

Artemifia. of our ordinary winters pretty well; though it will be 'for lighting the falutary balls, they employed mir- Artemifia; proper to have a plant or two in pots, which may be sheltered under a common hothed frame in winter, to preferve the species. The true wormwood is easily propagated in the same manner. The cuttings must be planted in a flady border, and duly watered during the fummer feafon, in which case, they will take root freely. In autumn some of the young plants should be potted, that they may be sheltered in winter; the others may be planted in a warm border, where they will live, provided the winter proves favourable. The other forts spread by their creeping roots; and require no culture, as they are very hardy, and will thrive anywhere.

Medicinal Uses. The feeds of the fantonicum are small, light, chaffy, composed as it were of a number of thin membranous coats, of a yellowish colour, an uupleasant smell, and a very bitter taste. They are celebrated for anthelmintic virtues (which they have in common with other bitters), and are sometimes taken in this intention, either along with melasses or candied with fugar. They are not very often met with genuine in the shops. The leaves of the sea, common, and Roman wormwoods, are used as stomachies, but are all very difagreeable; the Roman is the least so, and therefore is to be preferred; but the other two kinds are generally substituted in its place. The diffilled oil of wormwood is fometimes made use of to rub on the belly as a cure for worms.

The leaves of the vulgaris, or common mugwort, have a light aromatic smell, and an herbaceous bitterish tafte. They were formerly celebrated as uterine and antihysteric: an infusion of them is sometimes drank, either alone or in conjunction with other fubstances, in suppression of the mentional evacuations. This medicine is certainly a very mild one, and confiderably lefs hot than most others to which these virtues are attributed. In some parts of this kingdom, mugwort is of common use as a pot herb. It is now, however, very little employed in medicine; and it is probably with propriety that the London College have rejected it from their pharmacopœia.

The moxa, so famous in the eastern countries for curing the gout by burning it on the part affected, is the lanugo or down growing on the under fide of the leaves of a species of mugwort, supposed to be the same with our common fort. From fome dried famples of this plant which were brought over to this country, Mr Miller reckons them to be the same, differing only in fize; in which the East Indian kind is inferior to ours. He supposes that the lanugo of our mugwort would be equally efficacious. But according to Abbé Hift. of Grofier, "the leaves are more deeply indented than those of the common kind; it is also softer, and of a more filky texture. The ancient Chinese made great use of it in medicine. In all the northern provinces, the principal remedy for most diseases confisted in making deep punctures in the body, upon which small balls of the down of this plant were burnt. These punctures were made with needles of gold or steel, without drawing blood; and all the skill required in the physician, was to determine their number and depth, and where it was necessary to make them. It was necessary that the down of the mugwort should be very old; and, as every kind of fire was not proper

Vol. II. Part I.

rors made of ice or metal. " They caused the water externito freeze (fays the ancient text) in a round convex veffel; and the ice being prefented to the inn, collected its rays, and fet fire to the down of the plant." The literati are not at present agreed whether the secret of euring difeases by punctures be preserved; but theseddwny balls are still used instead of cupping glasses in apoplectic and lethargic cases. Girdles made of this down are also recommended for the sciatica, and those afflicted with the rheumatism in their legs are advised to quit their flockings with it. The mugwort destined for this purpose is gathered only in autumn; and care must be taken to pick that which has the shortest and softest down.

"In China, the juice of the common mugwort, when green, is used to stop spitting of blood; and the feast are employed for the same purpose. The dose of the latter is divided into two parts: one of which is reduced to ashes, and put into water, in which the other. has been boiled. These ashes, it is faid, when take any fauff, immediately ftop bleedings of the nofe. The Chinese presents this plant also with success for dyfenteries which proceed from weakness, and for pleurifies, and diforders of the flomach. An infution of the stalks and buttons of mug wort is recommended to old people inflead of tea .- Mugwort was formerly confidered there as a powerful prefervative against witchcraft. The ancient books rel te, that, in the third century of the Christian era, it was customary for people to gather this plant before funrile, and to fuspend it afterwards over their doors. The poets of the feventh century mention this custom, and describe the manner in which the streets of the capital were ornamented with it on the fifth day of the lifth moon; that is to fay, about midfummer.

" Of a species which hears prickles on the edges of its leaves, the leaves, when dried, are beaten with a wooden bat until the foft part is entirely separated from the fibres; and after they have been dipped in water mixed with faltpetre, they are used for tinder; no other kind is known at Pe-king; and it is equal to that of Europe. It appears that the ancient Chinese made use of the fost part of this plant for quilting, for making mattreffes, and even for cloth. They also employed it for manufacturing a kind of paper."

ARTEMISIUM (anc. geog.), a promontory on the north-east of Euboca (called Leon and Cale Alle by Ptolemy), memorable for the first fea engagements between the Greeks and Xerkes.

The Grecian fleet was flationed in the harbour; while that of the Persians, too numerous for any harbour to contain, had anchored in the road that extends between the city of Castanaa and the promontory of Sepias, on the coast of Thessaly.

The first line of their fleet was sheltered by the coast of Thessaly; but the other lines, to the number of seven, rode at anchor, at fmall intervals, with the prows of the vessels turned to the sea. When they adopted this arrangement, the waters were smooth, the sky clear, the weather calm and ferene: but on the morning of the fecond day after their arrival on the coast, the sky began to lower; the appearance of the heaven's grew threatening and terrible; a dreadful florm succeeded; and for three days raged with unabating fury. Four handred galleys were destroyed by its violence, besides a

fium .

Arthur.

Anemi- vast number of storeships and transports. Eight hundred thips of war, however, besides innumerable vessels of burden, failed into the Pegalean bay, and anchored in the road of Apheté, which, at the distance of a few miles, lies directly opposite to the harbour of Artemi-

From Gilof Greece.

The Grecians had posted centinels on the heights of hee's Hiffory Eubora to observe the consequence of the storm, and to watch the motions of the enemy. When informed of the difaster which had befallen them, they poured out a joyous libation, and facrificed with pious gratitude, to " Neptune the Deliverer."

The Persians, however, having recovered from the terrors of the storm, prepared for battle; and as they entertained not the smallest doubt of conquering, they detached 200 of their best failing vessels round the isle of Eubora to intercept the expected flight of the ene-

my through the narrow Euripus.

About sunset the Grecian fleet approached in a line; and the Persians met them with the confidence of victory, as their ships were still sufficiently numerous to furround those of their opponents. At the first fignal the Greeks formed into a circle, at the fecond they began the fight. Though crowded into a narrow compals, and having the enemy on every fide, they foon took 30 of their ships, and sunk many more. Night came on, accompanied with an impetuous florm of rain and thunder; the Greeks retired into the harbour of Artemisium; the enemy were driven to the coast of Theffaly.

By good fortune, however, rather than by defign, the greatest part of the Persian fleet escaped immediate destruction, and gained the Pegasean bay; but the thips ordered to fail round Euboca met with a more dreadful difatter. They were overtaken by the ftorm, after they had adventured further from the shore than was usual with the wary mariners of antiquity. Clouds foon intercepted the flars, by which alone they directed their course; and after continuing during the greatest part of the night the sport of the elements, they all perished miserably amidst the shoals and rocks of an unknown coaft.

The morning arose with different prospects and hopes to the Persians and the Greeks. To the former it discovered the extent of their misfortunes; to the latter it brought a reinforcement of 53 Athenian ships. Encouraged by this favourable circumstance, they determined again to attack the enemy, at the fame hour as on the preceding day, because their knowledge of the coast and their skill in fighting their ships rendered the dusk peculiarly propitious to their designs. At the appointed time, they failed towards the road of Aphete; and having cut off the Cilician squadron from the rest, totally destroyed it, and returned at night to Artemifium .- The Persian commanders being deeply affected with their repeated difasters, but still more alarmed at the much dreaded refentment of their king, they determined to make one vigorous effort for restoring the glory of their arms. By art and stratagem, and under favour of the night, the Greeks had hitherto gained many important advantages. It now belonged to the Perfians to choose the time for action. On the third day at noon, they failed forth in the form of a crescent, which was still sufficiently extensive to infold the Grecian line. The Greeks, animated by former

fuccels, were averle to decline any offer of battle; yet Artemiit is probable that their admirals, and particularly Themistacles, would much rather have delayed it to a more favourable opportunity. Raye, refentment, and indignation, supplied the defect of the barbarians in skill and courage. The hattle was longer, and more doubtful, than on any former occasion; many Grecian veffels were deftroyed, five were taken by the Egyptians, who particularly fignalized themselves on the side of the barbarians, as the Athenians did on that of the Greeks. The persevering valour of the latter at length prevailed, the enemy retiring, and acknowledging their fuperiority, by leaving them in possession of the dead and the wreck. But the victory cost them dear; since their vessels, particularly those of the Athenians, were reduced to a very shattered condition; and their great inferiority in the number and fize of their ships, made them feel more fensibly every diminution of strength.

ARTEMISIUM, a town of Oenotria, (Stephanus): now S. Agatha, in the Hither Calabria, on the river Pifaurus, or la Foglia, distant eight miles from the Tuscan sea .- Another of the Contestani, in Spain, (Strabo); otherwise called Dianium: now Denia, on the fea coast of Valencia.

ARTERIOTOMY, the opening an artery, with defign to procure an evacuation of blood. See Sur-

ARTERY, in anatomy, a conical tube or canal which conveys the blood from the heart to all parts of the body. See Anatomy, Nº 117,-125.

ARTHRITIS, in medicine, the Gour. See the

Index subjoined to Medicine.

ARTHRODIA, in natural history, a genus of imperfect crystals, found always in complex masses, and forming long fingle pyramids, with very short and slender columns.

ARTHRODIA, in anatomy, a species of articulation, wherein the flat head of one bone is received into a shallow focket in the other. The humerus and scapu-

la are joined by this species of articulation.

ARTHUR, the celebrated hero of the Britons, is faid to have been the fon of Uther Pendragon king of Britain, and to have been born in 501. His life is a continued scene of wonders. It is said that he killed four hundred and seventy Saxons with his own hand in one day; and after having fubdued many mighty nations, and inftituted the order of the Knights of the Round Table, died A. D. 542, of wounds which he received in The most particular detail of his story and battle. his exploits is that given by Geoffroy of Monmouth: but the probable there is so blended with the marvellous and the extravagant, that not only the truth of the whole, but even the reality of Arthur's existence, has been called in question.

In this controversy, Mr Whittaker has taken much pains to vindicate the existence, and discriminate between the real and the fabulous transactions, of the British worthy. " Many of the actions (he observes) attributed to Arthur by the Welsh chronicles of Birtain, are as abfurd in themselves as they are spurious in their authority. Written, as those narratives were, many centuries after the facts, and being merely the guthentic accounts of Arthur, embellished with the fictions and distorted by the perversions of folly; they are inconfishent equally with the state of the times, and

Arthur. the history of the continent and the island. And the ignorance of the forgers, and the credulity of their History of abettors, can be equalled only by the injudiciousness Manchester, and incredulity of the opponents to both. If some action of Arthur and Completing in these histories be edit. p. 31.3 counts of Arthur and Cunobeline in these histories be certainly spurious, others are as certainly genuine. And the relations of Suetonius, Dio, and Nennius, are not to be rejected, because of the falsehoods which imposture has ingratted upon them, and absurdity admitted with them.

"The existence of Arthur is evinced by that of the fables, which have at once annihilated his actions and his name with the misjudging critic. And the reafoner's own arguments really turn against himself, and demonstrate the point which they were intended to difprove. The annals of Wales have long laboured in Arthur's commendation. The Highlanders have long had a poetical history of his exploits in their own language. The whole island is in traditionary possession of his character; and 600 or 700 places within it are

still distinguished by his name.

. " The genuine actions of the chief are mentioned by his own historians, with a modelly and concileness that is no bad argument of the truth, and with a particularity of time and place that is a good evidence of the facts. They are noticed by men, whom the death of the hero had exempted from all temptation to flattery: they are recited by persons, whom a proximity to the times had precluded from all possibility of mistake: and they are attested by the bell historical authority, writers who lived cotemporary with him, authors who converfed with his warriors, and historians that wrote within a few years after him. He is spoken of as the honourable father of the British heroes by the aged Llomarch, a writer actually cotemporary with him, and some time resident at his court. One of his greater actions is incidentally recorded by Taliessin, an historical bard living under Maelgwn Gwined, who was a fovereign among the Britons in the days of Arthur, Gildas, and Llomarch. Another of his confiderable exploits is cafually intimated by Myrdhin Wyhlt or Merlinus Caledonius, who complains of the Severe treatment which he himself received from Rydderch Hael, a king cotemporary with Urien Reged, and engaged with him in a war against the Saxons on the death of Ida in 560. And all his actions are particularly recited by Nennius.

"An the Historia Britonum of this last author, Arthur's victories over the Saxons are thus recorded. The first battle was fought at the mouth of the river which is denominated Glem. The second, third, fourth, and fifth, were upon another river, that is called Duglas and lies in the region Linuis. The fixth was on a stream, which bears the appellation of Baffas. The seventh was in the wood of Celidon, that is, in Cat Coit Celidon. The eighth was at Castle Gunnion. And the ninth was at the city of the Legion. The tenth was on the bank of the river Ribroit; the eleventh at the hill Agned Cathregonion; and the twelfth at Mount Badon. These twelve battles of Arthur are described to us in the same manner as Vortimer's three. Only the general facts are mentioned, and only the common names of places are recited, in both. And from the whole air and aspect of the history, the remarkable concidencis with which the notices are given, and the great eafe with which the places are pointed Arthur. out, the detail appears to have been drawn up at the distance only of a few years from the transactions, and when these little references were sufficiently underflood."

Mr Whittaker proceeds to ascertain the scenes of Ar-

thur's battles; after which he gives a relation of them with a furprifing particularity. A fevere critic might be apt to fay, as Dr Kippis observes, that it requires all our faith in the author's judgment, as well as in his in-p. 43-64. genuity and learning, not to suspect that he sometimes allows too much scope to fancy and conjecture. However, the whole of what he hath advanced is fingularly curious, and deferves peculiar attention and confideration. And no one can help admiring the penetration with which he hath formed fuch a regular detail of facts, from the combined aid of history, romance, and tradition. According to Mr Whittaker, Arthur's principal exploits were against the northern Saxons, whilst he was only prince of the Silures, and Ambrofius was the dictator or pendragon of the Britons. " In a feries probably of five campaigns, and in a fuccession certainly of eleven victories, this great commander had repelled the Saxons from the north of Flavia, dislodged them from all Maxima, and dispossessed them of all Valentia. And these were successes so unchequered with missortunes, fo great in themselves, and so beneficial to the public, that the name of Arthur claims the first rank in the lift of military, and the better one of patriot, heroes." The twelfth battle of Arthur was fought in the fouth of England, after he was elected to the pendragonship, against Cerdie the Saxon. " This (lays Mr Whittaker) was a most extraordinary victory, and completes the circle of Arthur's military glories." In the author's account of this prince's conduct in peace, he afferts, that " Arthur faw that an appointment was wanted, which should at once be a more regular and more honourable fignature of merit; by the certainty of the honour and the greatness of the dignity, call out all the worth of all the worthy in the nation; and collect it round the throne of the pendragon. Accordingly he established a military order. It was the first that had ever been instituted in the island; and it has since been imitated by all the nations on the continent. By means of this affociation, Arthur raifed among thprovincials a general glow of ingenuous heroifm, the full spirit of chivalry that ever appeared in Europe; that manly and honourable gallantry of foul, which has made him and his worthics the fubject of romantie histories over all the west of it. By this, and this alone, could he have been what history represents him, the Reverend Father of the British Heroes in general, even to the conclusion of the fixth century, and nearly the middle of the feventh. The order naturally furvived its founder. And the members of it were denominated the Warriors of Arthur, though the persons were born half a century after his death." Mr Whittaker goes on to inform us, that under the prudent management of Arthur for 20 years together, a fair prospect dawned upon the Britons, and long scenes of future glorics opened to their imaginations. "But the gay vision was deltroyed at once by the commencement of a ci-

vil war. Many towns still remained in ruins, the me-

morial of the former wars, and the difgrace of the

Arthur. on the nation, and heroism became the tool of distension. And the dreadful combination of civil evils was begun and confummated, at once, by the death of the renowned Arthur in battle. Thus died the incomparable hero in 542."

To these observations it may not be improper to add the following account of the discovery of Arthur's tomb, which appears to be tolerably well authenticated. Henry II. who was the first of the Plantagenet line, being, in the last year of his reign, at Pembroke, and hearing there a Welsh bard singing to his harp the flory of Arthur, concluding with an account of his death, and burial in the churchyard of Glastonbury between two pyramids; the king infantly gave orders that the matter should be inquired into, and the body dug up. This was done as the king directed; and at the depth of seven feet was found a vast stone, whereon was fastened a leaden cross, with this inscription on the infide : Hic Jacet Sepultus Inclytus Ren Arturius in Infula Avalonia; i. e. " Here lies the famous King Arthur, buried in the ifle of Avalon." Digging still lower, they found the king's body in the trunk of a tree, his beautiful queen lying by him, with long flowing hair, in colour bright as gold, which however funk into dust when touched. The king's bones were very large fized; and in his skull there were ten wounds or more, all cicatrized, except that of which he died. This discovery was made in the year 1189, as Giraldus Cambrenfis tells us, who faw these bones, and examined the whole matter carefully. There was also a table containing this story, set up in the monastery of Glaftonbury, and the leaden crofs with the infcription remained there till the diffolution of the monastery, where it was feen by the great antiquary Leland, but what is become of it fince does not appear

Of the different places above alluded to as being diflinguished by our hero's name, and serving to evince his existence, the following may be mentioned as one

of the principal.

ARTHUR'S Scat, a high hill in the neighbourhood of Edinburgh, faid to have been so denominated from a tradition that King Arthur furveyed the country from its fummit, and had also descated the Saxons in itsneighbourhood. This hill rifes by a fleep and rugged afcent, till it terminates in a rocky point near 700 feet high from the base, being more than double the height of the cross on the top of St Paul's, Landon, which is 340 feet. On the fouth it is in many parts a perpendicular rock, composed of basaltic pillars, regularly pentagonal or hexagonal, about three feet in diameter, and from 40 to 50 feet in height. Contiguous, upon the west, and partly connected with it at the base, are Salifbury Craga, of inferior height, but exhibiting an appearance equally fingular and grand. They present to the city an awful front of broken rocks and precipices, forming a fort of natural amphitheatre of folid rock; and backward from the craggy verge above, the hill forms an extensive irregular slope, the surface affording pasture to numerous flocks of sheep. The crags, besides ares, spars, rock plants, and here and there, it is faid, some precious thenes, afford an inexhaustible supply of grassic for paving the firects and other purposes. In quarrying, a part of the crags has been worn down into a spacious fiels, having the appearance. of a lofty terrace, and fluctching a confiderable length.

From hence is a near and distinct prospect of the city, Artichoke with its environs and the adjacent country. But from the pinnacle called Arthur's Seat the view is more noble Article. and extensive. The traveller may here sit and survey at his eafe the centre of the kingdom, befides having a complete view of Edinburgh and its castle, on which he looks down as if feated among the clouds. In a word, the German ocean, the whole course of the Forth, the distant Grampians, and a large portion of the most populous and best cultivated part of Scotland, form a landscape sublime, various, and beauti-

The denomination of this hill, derived as above, has been adduced as an argument against those who dispute the existence of the British Arthur. That derivation, however, though probable, is not without uncertainty. For Arthur's Seat is faid to be derived, or rather corrupted, from A'rd Scir, a " place or neld of arrows," where people shot at a mark: And this not improperly; for among these cliffs is a dell or recluse valley, where the wind can fearcely reach, now called the Hunter's Bog, the bottom of it being a morals. The adjacent crags are supposed to have taken their name from the earl of Salisbury, who in the reign of Edward III. accompanied that prince in an expedition against the Scots.

ARTICHOKE, in botany. See CINARA.

ARTICLE, a clause or condition of a contract. treaty, &c. It is also a small part or division of a discourse, book, or writing, &c.

ARTICLE of Death, the last pange or agony of one

just expiring.

ARTICLE of Faith, is by some defined a point of Christian doctrine, which we are obliged to believe, ashaving been revealed by God himfelf, and allowed and

chablished as such by the church.

The thirty-nine articles were founded, for the most part, upon a body of articles compiled and published in the reign of Edward VI. They were first passed in the convocation, and confirmed by royal authority in the year 1562. They were afterwards ratified anew in the year 1571, and again by Charles I. The law requires a subscription to these articles of all persons ordained to be deacons or priests, 13 Eliz. cap. 12. of all clergymen inducted to any ecclefiaftical living, by the fame flatute, and of licenfed lecturers and curates, 13 Eliz. cap. 12. and 13 and 14 Ch. II. cap. 4. of the heads of colleges, of chancellors, officials, and commiffaries, and of schoolmasters. By 1 Will. III. cap. 18. diffenting teachers are to subscribe all, except the 34th, 35th, and 36th, and part of the 20th (and in the cafe of Anabaptists, except also part of the 27th); otherwife they are exempted from the benefits of the act of tolcration.

ARTICLE, in grammar, denotes a particle used in most languages for the declining of nouns, and denoting the feveral cases and genders thereof.

The use of articles arises chiefly hence, that in languages which have no different terminations, to expreis the different states and circumstances of nouns, there is forseshing required to supply that office.

The Latins have no articles; but the Greeks and most of the modern languages, have had recourse to them, for fixing and ascertaining the vague agnification of common and appellative names.

Article

The Greeks have their i, the eastern tongues their be emphaticum; the Italians their il, lo, and la. The Artificer. French their le, la, and les. The Germans their der, das, dat.

The English also have two articles, a and the; which being prefixed to fubfiantives, apply their general fignification to fome particular things.

Some grammarians make the article a diffinct part of speech; others will have it a pronoun, and others a noun adjective. See GRAMMAR.

Articles are of great service in a language, as they contribute to the more neat and precise expressing of feveral properties and relations, which must otherwise be loft. And hence one great disadvantage of such languages over the Latin, in that the article being cither expressed or left out, makes an alteration in the fense, which the Latins cannot diffinguish. Thus when the devil faid to our Saviour, Si tu es Filius dei, it may either be understood, "if thou art a son of God," or, " if thou art the son of God." The Italians even prefix articles to proper names, which do not naturally noed any, because they themselves signify things individually. Thus they say, il Ariosto, il Tasso, il individually. Petrarcha. Even the French join the article to the proper names of kingdoms, provinces, &cc. as la Suede, la Normandie. And we likewise annex it to the names of certain mountains and rivers; as, The Rhine, The Danube, the Alps, &c.

ARTICULATE sourps, are such sounds as express the letters, syllables, or words of any alphabet or language: fuch are formed by the human voice, and by some few birds, as parrots, &c.

ARTICULATION, or jointing, is the joining of bones together. See Anatomy, No 46.

ARTICULATION, in botany, is the connexion of parts that confitt of joints or knees, fuch as the pods of French honeyfuckles, which when ripe divide into fo many parts as there are knees or joints; also those parts of plants which swell into nodes or joints, and which usually send forth branches.

ARTIFICER, a person whose employment it is to manufacture any kind of commodity, as in iron, brafs, wool, &c. fuch are fmiths, brafiers, carpenters, &c. The Roman artificers had their peculiar temples, where they affembled and chose their own patron, to defend their causes: they were exempted from all personal fervices. Taruntenus Paternus reckons 32 species of artificers, and Constantine 35, who enjoyed this privilege. The artificers were incorporated into divers colleges or companies, each of which had their tutelar gods, to whom they offered their worship. Several of these, when they quitted their prosession, hung up their tools, a votive offering to their gods. Artificers were held a degree below merchants, and argentarii or momey changers, and their employment more fordid. Some deny, that in the earliest ages of the Roman state artificers were ranked in the number of citizens: others, who affert their citizenship, allow that they were held in contempt, as being unfit for war, and so poor that they could scarce pay any taxes. For which reason they were not entered among the citizens in the cenfor's books; the defign of the cenfus being only to fee what number of persons were yearly fit to bear arms, and to pay taxes towards the support of the state. It may be added, that much of the artificers bufinels was done by flaves and foreigners, who left little for the Artificial Romans to mind but their husbandry and war. By means of the arts, the minds of men are engaged in Artillery. inventions beneficial to the whole community; and thus prove the grand prefervative against the barbarism and brutality, which ever attend on an indolent and inactive stupidity.

By the English laws, artificers in wool, iron, steel, brais, or other metal, going out of the kingdom into any foreign country without license, are to be imprifoned three months, and fined in a fum not exceeding one hundred pounds. And fuch as going abroad, and not returning on warning given by our amballadors, &c. shall be disabled from holding lands by descent or devile, from receiving any legacy, &c. and be deemed aliens. Stat. 5. Geo. I. cap. 27. By 23 Geo. II. cap. 13. § 1. penalty is also inflicted on seducing artificers to go abroad. Ramazini has a treatife on the diseases of

ARTIFICIAL, in a general fense, denotes something made, fashioned, or produced by art, in contradistinction from the productions of nature.

ARTIFICIAL is also frequently used for factitious. Thus we have artificial fal ammoniac, artificial borax,

ARTIFICIAL Fire-works are compositions of inflammable materials, chiefly used on solemn occasions, by way of rejoicing. See Pyrotechny.

ARTIFICIAL Lightning. See ELECTRICITY and LIGHTNING.

ARTIFICIAL Lines, on a sector or scale, are certain lines to contrived, as to represent the Logarithmic fines and tangents; which, by the help of the line of numbers will solve all questions in trigonometry, navigation, &c. pretty exactly.

ARTIFICIAL Magnets. See MAGNETS.
ARTIGI, indeclinable, (Pliny); Artigis, (Pulemy); a town of the Turduli, in Betica. Now Albus

ARTILLERY, in its general fenfe, denotes the offensive apparatus of war, particularly of the missile kind. Among the French the term was anciently appropriated to ARCHERY. In its modern acceptation it fignifies fire-arms, mounted on their carriages and ready for action, with their balls, their bombs, their grenades, &c.

If we take the term in a more extensive meaning, it includes the powder, the matches, instruments for fire-works, the utenfils of ordnance, the machines which facilitate their motion and transport them, the vehicles over which they traverse rivers, every thing necessary to them, and all that enters into the form of a train of artillery.

The same word still farther extended in its meaning, likewife comprehends the men defined for the service of the artillery; the people who provide the artillery with materials and implements when engaged, the cannoniers, the bombardiers, the officers of every rank, and engineers of every kind.

By artillery is likewife understood the science which the officers of artillery ought to possess. This science teaches to know the nature of all the materials and ingredients which enter into the composition and the ftructure of every thing relative to the attiffery, fuch as nitre, fulphur, charcoal; the properties of air and artillery. fire; the composition and preparation of gunpowder; the materials for fireworks; the construction, proportions, &c. of the different warlike machines; the arrangement, movement, and whole management, of cannon, &c. in the field or in fieges, in fuch a manner, that each of them, according to the length of its tube and the diameter of its bore, may be fituated in the best place and at the properest distance for execution, and that the whole train taken together may reciprocally affift and support each other with the greatest advantage.

Artillery has undergone many changes from its origin to the present time. The artillery of the ancients were the catapulta, the balistae, the different kinds of slings, &c. In latter ages, the Franks used the hatchet as a miffile weapon, throwing it in the same manner as the Americans do theirs called the tomahawk. The Gascons and Genoese were excellent cross bow men. The Swiss owed their victories to their strength and skill in the use of the pike, halberd, and espadon or two-handed fword; and the victories of Creffy, Poictiers, and Agincourt, will occasion the valour and skill of the English archers to be transmitted down to latest

posterity. See Archery.

The chevalier Folard was extremely attached to the ancient machines first mentioned, and seemed even to prefer them to our fire arms: an opinion which must appear not a little extraordinary from such a person. Father Daniel might well be mistaken in the comparifon which he made between the effects of ancient and modern artillery, and in his conclusion that the latter was of little use: the situation of this good father removed him from the scenes of war and the opportunities of military experience. But it is assonishing, that one so learned in the military art as the commentator of Polybius, who had ocular demonstration of the fuccels of modern artillery, should have declared so violently against it. Whatever be the case with these authors and their maxims, it may be afferted, that cannon is one of the most fingular discoveries which have been made amongst men; and by little and little it has changed the whole art of war, and of consequence influenced the whole fystem of policy, in Europe. The era of artillery is dated from the battle of Cressy in 1346, because it is only from that day that cannons were mentioned in battle. Edward III. of England fuccessfully employed some pieces of artillery placed in the front of his army. The invention of artillery was then known in France as well as in England; but probably Philip VI. marched with fo much hurry and precipitation to attack his enemy, that he left his cannon as useless encumbrances behind him. The ignorance of that age in mechanical arts confiderably retarded the progress of artillery; and that of which they were then possessed was so unwieldy and imperfect, that they could not possibly discern its importance and efficacy in practice.

After the invention of gunpowder, the Spaniards were the first who armed part of their foot with muskets and harquebuffes, and mixed them with the pikes. In this they were foon imitated by most other nations; though the English had not entirely laid aside their favourite weapon the long bow, and generally taken to the use of fire arms, during the reign of Queen Elizabeth.

The first muskets were very heavy, and could not be

fired without a rest: they had matchlocks, and barrels Arnilery. of a wide bore, that carried a large ball and charge of powder, and did execution at a great diffance. The musketeers on a march carried only their rests and ammunition; and had boys to bear their muskets after them, for which they were allowed great additional pay. They were very flow in loading, not only by reason of the unwieldiness of the pieces, and because they carried the powder and balls separate, but from the time it took to prepare and adjust the match; so that their fire was not near to brisk as ours is now. Afterwards a lighter kind of matchlock mulket came into use; and they carried their ammunition in bandeliers, which were broad belts that came over the shoulder, to which were hung feveral little cases of wood covered with leather, each containing a charge of powder; the balls they carried loofe in a ponch, and they had also a priming horn hanging by their fide. Matchlocks were, about the beginning of this cratury, universally disused in Europe, and the troops were armed with firelocks; to which, much about the fame time, the bayonet being added, pikes also were laid aside; which latter change, whether it was for the better or not, is a point that still admits of dipute among the best nulitary writers, who are divided in their opinions about it. though most of them disapprove of it.

The old English writers call those large muskets calivers; the harquebus was a lighter piece, that could be fired without a rest. The matchlock was fired by a match, fixed by a kind of tongs in the ferpentine or cock, which by pulling the trigger was brought down with great quickness upon the priming in the pan, over which there was a fliding cover, which was drawn back by hand, just at the time of firing. There was a great deal of nicety are required to fit the match properly to the cock, to as to come down exactly true on the priming, to blow the this from the coal, and to grard the pen from the sparks that fell from it: a great deal of time was also lost in taking it out of the cock, and returning it between the fingers of the left hand, every time that the piece was fired; and wet weather often rendered the matches useless However, most writers allow that they were very fure, and

less apt to mils fire than the firelock.

The firelock is fo called, from producing fire of itfelf, by the action of the flint and fleel. The most ancient invention of this fort is the wheel lock, which we find mentioned in Luigi Collado's Treatife of Artillery. printed at Venice, 1586, as then lately invented in Germany. This fort of lock was used till within these hundred years, especially for pistols and carabines. It was composed of a folid scel wheel, with an axis, to which was fastened a chain, which, by being wound round it drew up a very strong spring; on pulling the trigger, the spring acting, whirled the wheel about with great velocity, and the friction of the edge of it (which was a little notched) against the stone produced the fire; the cock was made to as to bring the stone upon the edge of the wheel, part of which was in the pan, and touched the priming; they used any common hard peeble for that purpose, which served as well as slint.

These locks were inconvenient, took time to wind up (or span, as they termed it), and sometimes would not go off; an instance of which may be seen in Lud-

low's Memoirs.

Artillery.

When the firelock, fuch as we now use, was invented, we cannot afcertain; it is called by writers of about the middle of the last century, a fnaphane or fnaphance, which being the Dutch word for a firelock, feeins to indicate that it is a Dutch invention, and that we took it from them. But Ward, in his Animadversions of War, printed in 1639, p. 502, after describing the exescife of the firelock, pillol, and carabine (by which he means the wheel-lock), fays, that as most of our pieces go with English locks, which differ from firelocks, he shall add the method of handling them; and then gives the exercise of the snaphine carabine; by which it appears, that there was little or no difference between that and the pieces now in use. The more modern writers call it a fusce, from the French word fusil; whence the name of fufileers is still continued to feveral of our regiments, which were the first that were armed with them on the difuse of matchlocks.

They used the musket and reit in England so late as the beginning of the civil wars, as may be seen in Col. Barisse's Young Artillery Man, printed at Lon-

don, 1643.

Figuera, in his embassy in 1518, relates, that the Persians would neither make use of infant y nor of artillery, because by them the impetuosity of attack and the facility of retreat were equal, encumbered and retarded: in these expedients alone their address and their glory consisted. This method of advancing and recalling is widely different from the present conduct of war, as the artillery in armies is now prodigiously multiplied, and must be transported to every place where any body of troops whatever is destined to operate.

The length and diameter of cannon has been much diminished, which must like a portionably diminish their weight. It is by long practice and experience that they have discreted how much might be deduced from their magnitude in both these respects with propriety, without hurting the grand effects which, on some occasions, it is necessary they should produce, by rendering them more lasty to be wielded, which was the advantage pursue by lessening their fize. See further the articles Cartion, Gunnery, and Projectiles.

Improvements, however, are still making, and will probably long continue to be made, in these ignivo-mous machines that mock the thunder, which though they seem to be invented for the destruction of the human race and the subversion of empires, have yet by their effects rendered war less savage and less sanguine; political alliances have been more free essuly conciliated among all nations, compuells are become less frequent and less rapid, and successes in war have been

more easily reduced to calculation.

Wealth uf

Nation

Vol. [1].

* P- 70.

The change introduced in the military at by the modern artillery, Dr Smith observes, has enchanced greatly both the expence of excepting and disciplining any particular number of soldiers in time of peace, and that of employing them in the of wer. Both their arms and their ammunition are become more expensive. A muster is a more expensive machine than a javelin or abow and arrows; a cannon or a mortar, then a balista or a cataputa. The pewder which is spent in a modern review is lost irrecoverably, and occasions a very considerable expense. The javelins and arrows which were

thrown or shot in an ancient one, could easily be picked Artillery. up again, and were besides of very little value. The cannon and the mortar are not only much dearer, but much heavier machines than the balists or catapults, and require a greater expence, not only to prepare them for the sield, but to carry them to it. As the superiority of the modern artillery too over that of the ancients is very great, it has become much more difficult, and consequently much more expensive, to fortify a town so as to resist even for a few weeks the attack of that superior artillery.

In modern war the great expence of fire arms gives an evident advantage to the nation which can belt afford that expence; and confequently, to an opulent and civilized, over a poor and barbarous nation. In ancient times, the opulent and civilized found it difficult to defend themfelves againft the poor and barbarous nations. In modern times the poor and barbarous find it difficult to defend themfelves againft the opulent and civilized. The invention of fire arms, an invention which at first fight appears to be so permicious, is certainly favourable both to the permanency and to the extension of civilization.

It has to many appeared matter of furprise, that the battles of the ancients should be described with an order, perspicuity, and circumstantial minuteness, which are not to be found in the military writers of modern times. Scholars have endeavoured to explain this difference by observing the immense disproportion, in point of dignity and abilities, between the military historians of modern Europe and those of Greece and Rome. But the difficulty will be better folved, Dr Gillies thinks, by reflecting on the changes introduced into the art of war by the change of artillery; which in military operations, form the pivot on which the whole turns. 1. From the nature of fire arms, modern battles are involved in fmoke and confusion. 2. From the same cause, modern armies occupy a much greater extent of ground, and begin to act at much greater distances: which renders it more difficult to observe and afcertain their manœuvres. 3. The immense train of artillery, ammunition, &c. required in the practice of modern war, gives a certain immobility to our armies, which renders it impossible to perform, without great danger, those rapid evolutions in fight of an encmy, which fo often decided the battles of the ancients. With us, almost every thing depends on the judicious choice of ground, a matter requiring great military genius, but not admitting the embellishments of hislorical description.

In the battles of the Greeks and Romans, the extraordinary difproportion between the numbers flain on the fide of the victors and the vanquished has been observed as another remarkable circumstance. But this necessarily resulted from the nature of their arms. Their principal weapons being not missile, but manual, armics could not begin to act till they had approached so near to each other, that the conquered found themselves cut off from all possibility of retreat. In modern times, such consequences seldom take place. The use of sire arms (which often renders the action itself more bloody, furnishes the deseated party with various means of retreating with considerable safety. The sphere of military action is so widely extended in modern times, that before the victors can run over the space which se-

parates them from the vanquished, the latter may fall back, and proceed with little loss beyond their reach; Artobriga and should any village, hedge, ravine, &c. be found in their way, may often check the ardour of the pursuers. Upon these considerations, the invention of gunpowder and modern artillery may be faid to have faved the effufion of human blood. Equestrian engagements (fince the principles on which cavalry act remain nearly the fame in every age) are still distinguished by similar circumstances to those which appear so extraordinary in the battles of antiquity.

> ARTILLERY Park, the place in the rear of both lines in the army, for encamping the artillery, which is drawn up in lines, of which one is formed by the guns; the ammunition waggons make two or three lines, 60 paces behind the guns, and 30 distant from one another; the pontoous and tumbrils make the last line. The whole is furrounded with a rope which forms the park : the gunners and matroffes encamp on the flanks; and the bombardeers, pontoon men, and arti-

dicers, in the rear.

ARTILLERY Train, a certain number of pieces of ordnance mounted on carriages, with all their furniture fit for marching.

ARTILLERY Company, a band of infantry, confishing of 600 men, making part of the militia or city guard

of Landon.

ARTIST, in a general fense, a person skilled in some art. Mr Harris defines an artist to be, " A person posfeffing an habitual power of becoming the cause of some effect, according to a lystem of various and well ap-

proved precepts." See ART.

Evel. Difourse of nedals.

We are told * of a privilege granted at Vicenza to artists, like that of clergy in England: in virtue thereof criminals adjudged to death fave their lives if they can prove themselves the most excellent and consummate workmen in any useful art. This benefit is allowed them in favorom artis, for the first offence, except in some particular crimes, of which coining is one; for here the greater the artist, the more dangerous the person.

ARTIST (Artista,) in an academical sense, denotes a philosopher or proficient in the faculty of arts.

In the early ages of universities, the feven liberal arts completed the whole course of study, or philosophy, as it is called: whence the masters of this faculty were denominated Artists. What they understood by the liberal arts used to be summed up in the following Latin verfe:

Lingua, Tropus, Ratio, Numerus, Tonus, Angulus, Aftra.

ARTIST is more peculiarly used, by Paracelsus and other adepts, for a chemist or alchemist.-We find frequent mention, in authors of this class, of Elias Artista, or Elias the artist, who is to come some time before the diffultion of the world, and reftore and make perfect all arts and sciences, but especially the gold making art; and wher in a truly golden age, or millennium. The lower and meaner things in this sublime art, Paracelfus observes, God has permitted to be already discovered; but for the greater and more important matters, as the transmutation of other metals into gold, they are referred to the coming of Elias the artist.

ARTOBRIGA, a town of Vindelicia (Ptolemy):

Now Alizburg, in Bayaria, on the Danube, below In-Artocarpus golftadt (Aventinus): but Cluverius supposes it to be Lebenau, on the Saltzbach, below Lauffen, in the archbishopric of Saltzburg.

ARTOCARPUS (from sever; bread, and seguer, fruit), the BREAD-FRUIT TREE: A genus of the monandria order, belonging to the monœcia class of plants. It has a cylindric amentum or catkin, which thickens gradually, and is covered with flowers; the male and female in a different amentum. In the male the calyx is two-valved, and the corolla is wanting. In the female, there is no calyx nor corolla; the flylus is one,

and the drupa is many celled.

Though this tree has been mentioned by many vovagers, particularly by Dampier, by Rumphius, and by Lord Anfon, yet very little notice feems to have been taken of it till the return of Captain Wallis from the South seas, and fince that time by others who have touched at Otaheite and fome countries in the East Indies. Captain Dampier relates, that in Guam, one of the Ladrone islands, " there is a certain fruit called the bread fruit, growing on a tree as big as our large apple trees, with dark leaves. The fruit is round, and grows on the boughs like apples, of the biguess of a good penny loaf: when ripe, it turns yellow, foft, and fweet; but the natives take it green, and bake it in an oven till the rind is black: this they scrape off, and eat the infide, which is foft and white, like the infide of new baked bread, having neither feed nor stone; but if it is kept above 24 hours it is harsh. As this fruit is is feafon eight months in the year, the natives feed upon no other fort of bread during that time. They told us that all the Ladrone islands had plenty of it. Ine-

ver heard of it in any other place."

Rumphius, after describing the tree, observes, that " the fruit is shaped like a heart, and increases to the fize of a child's head. Its furface or rind is thick, green, and covered everywhere with warts of a quadragonal or hexagonal figure, like cut diamonds, but The more flat and smooth these warts without points. are, the fewer feeds are contained in the fruit, and the greater is the quantity of pith, and that of a more glutinous nature. The internal part of the rind, or peel, confifts of a fleshy substance, full of twifted fibres, which have the appearance of fine wool; these adhere to, and in some measure form it. The fleshy part of this fruit becomes fofter towards the middle, where there is a small cavity formed without any nuts or seeds, except in one species, which has but a small number, and this fort is not good, unless it is baked or prepared fome other way; but if the outward rind be taken off, and the fibrous flesh dried and afterwards boiled with meat as we do cabbage, it has then the taste of artichoke bottoms. The inhabitants of Amboyna drefs it in the liquor of cocoa nuts: but they prefer it roafted on coals till the outward part or peel is burnt. They afterwards cut it into pieces, and cat it with the milk of the cocoa nut. Some people make fritters of it, or fry it in oil; and others, as the Sumatrans, dry the internal foft part, and keep it to use instead of bread with other food. It affords a great deal of nourishment, and is very fatisfying, therefore proper for hardworking people; and being of a gentle aftringent quality, is good for persons of a laxative habit of body

It is more nourifhing boiled in our manner with fat meat than roafted, on coals. The milky juice which diffils from the trunk, boiled with the cocoa nut oil. makes a very strong bird lime. This tree is to be found on the eastern parts of Sumatra, and in the Malay language is called foccus and foccum capas. It grows likewife about the town of Bantam in Java, and in Ballega and Madura, and is known there by the name of foccum."

In Anfon's voyage we are informed, "that the rima, or bread fruit tree, is common in all the Ladrone islands and some of the Philippines. It is somewhat larger than our apple tree, and bears a broad dark coloured leaf with five indentures on each fide. The fruit hangs on the boughs like apples; and is of the fize of a penny loaf, with a thick tough rind, which when full ripe turns yellow. The natives gather it before it is quite ripe, and bake it till the crust is pretty black; then they rasp it, and there remains a pretty loaf, with a tender yellow crust, and the crumb of it is soft and fweet as a new baked roll: it is without any feeds or stones. This fruit the inhabitants enjoy for about feven months; during which they never eat any other kind of bread: but they are obliged to bake it every day; for when it grows a little stale, it becomes harsh and husky, somewhat like the potatoe bread made in the west of England. There is, however, a remedy for this; which is cutting the loaf into flices when it is new, and drying it in the fun, by which it is changed into the pleasantest rusk that can be caten."

Captain Cook, in his voyage, observes, that this fruit not only serves as a substitute for bread among . Hawker the inhabitants of Otaheite and the neighbouring w.rib's ac- illands, but also, variously dressed, composes the princount of Cap-cipal part of their food. It grows on a tice that is about the fize of a middling oak; its leaves are frequently a foot and a half long, of an oblong shape, deeply sinuated like those of the fig tree, which they resemble in colour and confishence, and in the exuding of a milky juice upon being broken. The fruit is about the fize and shape of a new born child's head; and the surface is reticulated to not much unlike a truffle; it is covered with a thin skin, and has a core about as big as the handle of a small kuife. The eatable part lies between the skin and the core; it is as white as fnow, and fomewhat of the confiftence of new bread; it must be rousted before it is eaten, being sirst divided into three or four parts; its talle is inlipid, with a flight sweetness somewhat resembling that of the crumb of wheaten bread mixed with a Jerusalem artichoke. This fruit is also cooked in a kind of oven, which renders it foft, and fomething like a boiled potato; not quite lo farinaceous as a good one, but more so than those of the middling fort. Of the bread fruit they also make three dishes, by putting either water or the milk of the cocoa nut to it, then beating it to a paste with a stone petile, and afterwards mixing it with ripe plantains, bananas, or the four paste which they call mabie.

The makie, which is likewise made to serve as, a fuccedaneum for ripe breadfruit before the leafon comes on, is thus made: The fruit of the bread tree is gathered just before it is perfectly ripe; and being laid in heaps, is chosely covered with leaves: in this state it undergoes a fermentation, and becomes difagreeably

Voc. II. Part L.

fweet; the core is then taken out entire, which is done Arocara by gently pulling out the flalk, and the reft of the Arton, fruit is thrown into a hole which is dug for that purpose generally in the houses, and neatly lined in the bottom and fides with grafs: the whole is then covered with leaves and heavy stones laid upon them; in this flate it undergoes a second fermentation, and becomes four, after which it will fuffer no change for many months. It is taken out of the hole as it is wanted for use; and being made into balls, it is wrapped up in leaves and baked: after it is dreffed, it will keep five or fix weeks. It is eaten both cold and hot; and the natives feldom make a meal without it, though to Europeans the tafte is as dufagreeable as that of a pickled olive generally is the first time it is eaten. The

fruit itself is in season eight months in the year, and the mahie supplies the inhabitants during the other

four. To procure this principal article of their food (the bread fruit), colls these happy people no trouble or labour except climbing up a tree : the tree which produces it does not indeed grow spontaneously; but if a man plants ten of them in his life time, which he may do in about an hour, he will as completely fulfil his duty to his own and future generations, as the native of our less temperate climate can do by ploughing in the cold of winter, and reaping in the fummer's heat, as often as these seasons return; even if, after he has procured bread for his prefent household, he should convert a lurplus into money, and lay it up for 'his children.

There are two species of artocarpus, viz. the incufus, with gashed leaves; and the integrafolia, with entire leaves. There is also faid to be another distinction, into that which bears fruit with flones or feeds, and that in which the fruit has none. The parts of fructification of that tree which bears the fruit without flones are defective. The amentum, or catkin, which contains the male parts, never expands. The flyling or female part of the fruit, are likewise deficient. From which it follows, that there can be no flones or feeds, and therefore that this tree can be propagated only by fuckers or layers; although it is abundantly evident, that it must originally have proceeded from the feed-bearing bread fruit tree. Inflances of this kind we sometimes find in European fruits; such as the barberry, and the Corinthian grape from Zant commonly called currants, which can therefore be increafed only by layers and cuttings. Dr Solander was affured by the oldest inhabitants of Otaheite and the adjoining islands, that they well remembered there was formerly plenty of the feed bearing bread fruit; but they had been neglected upon account of the preference given to the bread fruit without feeds, which they propagate by fuckers.

ARTOIS, a province of France, and one of the finest and most fertile in the whole kingdom; formerly it was one of the 17 provinces of the Netherlands, but now belongs entirely to France. The names of Artois, and Arras its capital, are derived from the Atrebates, a people of Galha Belgica, mentioned by Julius Cæfar. Its greatest length from north to fouth is about 24 leagues, and its breadth about 12, being bounded to the fouth and well by Picardy, to the east by Hainault, and to the north by Flanders. A con-

fiderable

Arum

Arucia,

Artolica liderable trade is carried on in the province in grain, flax, hops, wool, and linen cloth. The states, who meet regularly once a year, confift of the clergy, nobility, and commoners; and fit generally a fortnight at Arras: their chief business is to deliberate on the ways and means to raife the money which the king demands of them, and which usually amounts to about 400,000 livres, exclusive of forage money. The most considerable places in Artois are, Arras the capital, Bapaume, Bethune, St Venant, and St Omer.

ARTOLICA (anc. geog.), a town of the Salassii in Gallia Cifpadana, (Antonine); at the foot of the Alps: now called la Tuile by the inhabitants, a hamlet of Savoy, in the duchy of Aoust, at the foot of

Mount St Bernard the Lefs.

ARTOTYRITES, a Christian sect, in the primitive church, who celebrated the eucharist with bread and cheefe, faying, that the first oblations of men, were not only of the fruits of the earth, but of their flocks. The word is derived from agres, bread, and ruges,

The Artotyrites admitted women to the priesthood and episcopacy; and Epiphanius tells us, it was a common thing to fee feven girls at once enter into their church, robed in white, and holding a torch in their hand; where they wept, and bewailed the wretchednels of human nature, and the miseries of this life.

ARUA (anc. geog.), a town of Bætica, of the refort of the Conventus Hispalentis, (Pliny): now Alclea, a citadel of Andalufia, on the Bætis, or Guadal-

quiver, feven leagues above Seville.

ARVALES FRATRIS, in Roman antiquity, a college of 12 priefts, influtted by Romulus, and chofen out of the most noble families, himself being one of that body: they affitted in the facrifices of the ambervalia annually offered to Ceres and Bucchus, for the prosperity of the fruits of the earth; when they wore on their heads crowns made of ears of corn .- The original of this inflitution was as follows: Acca Laurentia, Romulus's nurse, was accustomed once a-year to make a folemn facrifice for a bleffing on the fields, her 12 fons always affilting her in the folemnity; but at last losing one of her loss, Romulus offered himself to Supply his place, and gave this small society the name of Arvales fratres. This order was in great repute at Rome: they held the dignity for life, and never loft it upon account of imprilonment, banishment, or any other a. cident.

ARUBA, a small island on the coast of Terra Firma, subject to the Dutch, and situated in W. Long.

69. 30. N. Lat. 12. 30.

ARUCI, (anc. geog.), a town of the Celtici, in the north of Lusitania, (Antonine, Inscription); called also Aruci Novam, to diffinguish it from the following: Now supposed to be Moura, a small city of Portugal, near the confluence of the Ardila and Guadalquiver.

ARUCI VETUS, (anc. geog.), a small city of the Turdetani, in Bætica, (Ptolemy); now Aroche, a hamlet of Andalusia, on the confines of Portugal and Estremadura, on the river Gama, feven leagues to the east of Aruci Novum or Moura. From it a mountain, in its neighbourhood, takes the name Arucitanus. Now la Sierra de Aroche.

ARUCIA, (anc. geog.), a town of Illyria, in the

inland parts of Liburnia, (Ptolemy). Now Bregna, ac- Arvani cording to fome; but Ottofchatz, according to others; a citadel of Morlachia.

ARVERNI, an appellation early used for the capital of the Arverni, according to the custom of the latter ages of naming towns from the people; it was formerly called Nemoffus, (Straho). The Arverni, a brave and ancient people, and one of the most powerful nations of Gaul, claimed affinity with the Romans, as descendants from Antenor, (Lucan): and after their conquest by the Romans, their ancient liberty was preferved to them on account of their bravery, (Pliny). Above 1000 years ago the town was called Clarus Mons, from its situation, (Valesius.) Now Clermont, in Auvergne. E. Long. 3. 20. N. Lat. 45. 42.

ARVIL SUPPER, a feast or entertainment made at funerals, in the north part of England. Arvil bread is the bread delivered to the poor at funeral folemnities: and arvil, arval, arfal, are used for the burial or fune-

ral rites; as,

Come, bring my jerkin, Tibb, I'll to the arvil; You man's dea scuy seoun, it makes me marvil. Yorkfb. Dial. p. 58.

ARVIRAGUS, an ancient British king who flourished in the time of the emperor Domitian. He gained a complete victory over Claudius: but being foon after belieged in the city of Winchester, he made a treaty with the Romans, and married the emperor's daughter Genuissa. This monarch lived to a good old age: he confirmed the ancient laws, enacted new ones,. and liberally rewarded persons of merit.

ARUM, WAKEROBIN, OF CUCROW-PINT: A genus of the polyandria order, belonging to the gynandria class of plants; and in the natural method ranking under the 2d order, Piperite. The fpatha is monophyllous, and cowl-shaped; the spadix is naked above, female below, and stamen'd in the middle.-The

Species are 22; of which the most remarkable are the following. 1. The maculatum, or common wakerobin, grows naturally in woods and on shady banks in most parts of Britain. The leaves are halberd-shaped, very entire, and spotted; the berries numerous, growing in a naked cluster. The flowers appear in April; and their wonderful structure hath given rife to many disputes among the botanists. The receptacle is long, in the shape of a club, with the seed buds surrounding its base. The chives are fixed to the receptacle amongst the feed buds, fo that there is no occasion for the tips to be supported upon threads, and therefore they have none; but they are fixed to the fruit stalk, and placed between two rows of tendrils: the point in dispute is, what is the use of those tendrils? 2. The proboscidium. 3. The arisarium. 4. The tenuisolium. These three species have usually been separated from this genus, and diffinguished by the general name of arisarum or friar's cowl, on account of the refemblance of their flowers to the shape of the cowls worn by friars. The flowers appear in April. 5. The italicum, is a native of Italy, Spain, and Portugal. The leaves rife a foot and au half high, terminating in a point; they are very large, and finely veined with white, interspersed with black fpots, which, together with the fine shining green, make a pretty variety. The flowers grow near a foot high; becomes at length an almost insipid farinaceous sub- Arunday

This root is a powerful flimulant and attenuant. It is reckoned a medicine of great efficacy in some cachecu tic and chlorotic cases, in weakness of the stomach occasioned by a load of viscid phlegm. Great benefit has been obtained from it in rheumatic pains, particularly those of the fixed kind, and which were feated deep. In these cases it may be given from 10 grains to a scruple of the fresh root twice or thrice a day, made into a bolus or emulfion with unchous and mucilagiaous fubstances, which cover its pungency, and prevent its making any painful impression on the tongue. It generally excites a flight tingling fentation through the whole habit, and when the patient is kept warm in bed, produces a copious sweat.

The arum was formerly an ingredient in an officinal preparation, the compound powder; but in that form its virtues are very precarious. Some recommended a tincture of it drawn with wine; but neither wine,

water, nor spirits, extract its virtues.

ARUNDA, a town of Hispania Beetica, on the Anas, or Guadiana, (Ptolemy, Plmy): Now faid to be Ronda, in the province of Granada, on the confines of Andalusia. W. Long. 5. 40. Lat. 36. 26.

ARUNDEL (Thomas), archbishop of Canterbury in the reigns of Richard II. Henry IV. and Henry V. He was the fecond fon of Robert earl of Arundel and Warren, and brother of Richard carl of Arundel who was beheaded. At 22 years of age, from being archdeacon of Taunton he was raifed to the bishopric of Ely, the 6th of April 1375, in the reign of Edward III. He was a great benefactor to the church and palace of this fee; among other donations he gave a curious table of maffy gold, adorned with precious stones, which had been given to Prince Edward by the king of Spain, and fold by the latter to Buhop Arundel. In 1386, he was appointed lord chancellor of England; two years after, he was translated to the fee of York; and, in 1306, was advanced to the archicoifcopal fee of Canterbury, when he refigned the chancellorship. This was the first instance of the trausletion of an archbifliop of York to the fee of Canterbury. Scarcely was he fixed in this fee, when he had a contell with the university of Oxford about the right of vifitation. The affair was referred to King Richard, who determined it in favour of the archbishop. At his vifitation in London, he revived an old conflitution, by which the inhabitants of the respective parishes were obliged to pay to their rector one halfpenny in the pound out of the rent of their houses. In the second year of his translation, a parliament being held at London, the commons with the king's leave impeached the archbishop, together with his brother the carl of Arundel, and the duke of Gloucester, of high treason. The archbishop was sentenced to be banished, and within forty days to depart the kingdom on pain of death. He retired first to France; and then to the court of Rome, where Pope Boniface IX. gave him a kind reception. About this time the duke of Lancaster (afterwards Henry IV.) was in France, having been banished by King Richard. The nobility and others, tired with the oppressions of Richard, solicited the duke to take the crown. This their request they drew up in a

Arom. and have very long upright spathas, which are of a pale green. They appear in the end of April, or beginning of May. 6. The dracunculus, or common dragon, grows naturally in most of the southern parts of Europe. It hath a straight stalk three or four feet high, which is spotted like the belly of a snake : at the top it is spread out into leaves, which are cut into several narrow fegments almost to the bottom, and are spread open like a hand; at the top of the stalk the flower is produced, which is in shape like the common arum, having a long spatha of a dark purple colour, standing erect, with a large pistil of the same colour, so that when it is in flower it makes no unpleasing appearance; but the flower hath fo flrong a scent of carrion, that few people can endure it, for which reason it hath been banished most gardens. 7. The trilobatum, or arum of Ceylon, is a native of that island and some other parts of India; fo is very impatient of cold. It is a low plant: the flower rifes immediately from the root, flanding on a very short footstalk: the spatha is long, erect, and of a fine scarlet colour, as is also the pistil. 8. The colocosia. 9. The divaricatum, with spear-shaped leaves. 10. The peregrinum, or elder. 11. The esculentum, or catable arum. 12. The sagittifolium, or greatest Egyptian arum. All these species have mild roots, which are eaten by the inhabitants of the hot countries, where they grow naturally; and some of them are cultivated by the inhabitants of the fugar colonies, where their roots are constantly eaten, as also the leaves of some of them, particularly those of the esculentum, which they call Indian kale; and which, in those countrics where many of the esculent vegetables of England are with difficulty produced, proves a good fuccedaneum. 13. The arborescens, or dumb cane, is a native of the fugar islands and warm parts of America, where it grows chiefly on low grounds. All the parts of it abound with an acrid juice; fo that if a leaf or part of the stalk is broken and applied to the tip of the tongue, it occasions a very painful sensation and a great defluxion of faliva. The stalks of this plant are sometimes applied to the mouths of the negroes by way of punishment.

Culture. All the species of this plant are hardy, except the trilobatum and the arborescens. The former must be kept constantly in a stove, and the last in a moderate hot-bed. The arborescens is propagated by cutting off the stalks into lengths of three or four joints, which must be left to dry six weeks or two months; for if the wounded part is not perfectly healed over before the cuttings are planted, they will rot and decay. They are then to be planted in small pots filled with light fandy earth, and plunged in a modetate hot-bed of tan, observing to let them have little

water till they have taken good root.

Medicinal Uses. The roots of the maculatum and dracunculus are used in medicine, and differ in nothing but that the latter is somewhat stronger than the former. All the parts of the arum, particularly the root, have an extremely pungent, acrimonious tafte; if the root be but lightly chewed, it continues to burn and vellicate the tongue for some hours, occasioning at the fame time a confiderable thirst; these symptoms are alleviated by butter, milk, or oily liquors. Dried and kept for some time, it loses much of its acrimony, and

Armsel letter, and fent it over by faithful messengers to Archbishop Arundel, desiring him to be their advocate on this occasion with the duke. The archbishop, being a fellow fufferer, gladly accepted the office; and went with the messengers to the duke at Paris, where they delivered the letters from the nobles and commons of England, and the archbishop seconded them with the best arguments he could invent. The inviting offer. after some objections which were easily obviated, the duke accepted; and upon his accession to the throne, Arundel, who had returned with him to England, was restored to his sec. In the sirst year of this prince's reign, Arundel summoned a synod which sat at St Paul's. The next year the commons moved that the revenues of the church might be applied to the fervice of the public; but Arundel opposed the motion with fuch vigour, that it was thrown afide. In the year 1408, Arundel began to exert himself against the Lollards, or Wickliffites; and his zeal for suppressing that sea earried him to feveral unjustifiable feverities against the heads of it, particularly against Sir John Oldcastle and Lord Cobham. He also procured a synodical conflitution, which forbade the translation of the Scriptures into the vulgar tongue. This prelate died at Canterbury, Feb. 20. 1413, of an inflammation in his throat, with which he was feized (as it is pretended) whilft he was pronouncing fentence upon Lord Cobham. The Lollards afferted this to be a judgment from God; and indeed Bilhop Goodwin speaks in the same manner, faying, " He who had withheld from the people the word of God, the food of the foul, by the just judgement of God had his throat so closed, that he could not speak a single word, nor swallow meat or drink, and was fo starved to death." He was buried in the cathedral church of Canterbury, near the west end, under a monument erected by himfelf in his lifetime. To this church he was a confiderable benefactor: for he built the lantern-tower and great part of the nave; gave a ring of five bells, called from him Arundel's ring; several rich vestments, a mitre enchased with jewels, a filver gilt crofier, and two golden chalices.

A THE

Arunder, a borough and market town in Suffex, feated on the north-well fide of the river Arun, over which there is a bridge. It had a harbour, wherein a fhip of 100 tons burden might ride; but the fea had ruined it so far, that, in 1733, an act passed for repairing it, and for erecting new piers, locks, &c. The castle, which gives the title of earl to its possessors, is feated on the cast of the Tame, and is reputed to be a mile in compals. It fends two members to parliament; and is 55 miles fouth-west-by-south of London, and 10 miles east of Chichester. Arundel is the premier carldom in England, belonging to the illustrious family of Norfolk; and is the only title in England that goes along with the lands. W. Long. o. 25. N. Lat. 50. 45.

ARUNDEL Oil, in the materia medica. At Bombay, Combroon, and Surat, in the East Indies, there grows a time which bears a nut enclosed in a rough huse. With resembles much the horse-chesnut; and the kerner of the nut yields an oil by expression, which is of a strative nature. A tea-foourful of it is recis of a stative nature. A tea-spoonful of it is reckonding the. The tree goes by the name of the Arunate as Bombay, and its oil by that of the Arun-

del oil. Mr Sinclair, one of the furgeons belonging to Arunde the royal regiment of artillery, who was formerly furgeon to an East India ship, gave Dr Monro of London a small bottle full of this oil, which he said was much used for the cure of the dysentery in India, and that he had given it in four recent cases of dysentery with succefs .- Dr Monro thinks it probable that this is the oil of the purging auts mentioned in Dale's Pharmacologia, which are got from the tree called Lignum Moluccenfe, Pavana didum, fruitu avellana, J. B. 1. 342; and pinus Indica, nucleo purgante, C. B. 492; and the palma Christi Indica, Tournefort Mat. Med.

ARUNDELIAN MARBLES, OXFORD MARBLES, or Parian Chronicle, are ancient stones (as has been supposed), whereon is inscribed a chronicle of the city of Athens, engraven in capital letters in the island of Paros, one of the Cyclades, 264 years before Jefus Christ. They take their first name from Thomas earl of Arundel, who procured them out of the East, or from Henry his grandfon, who presented them to

the university of Oxford.

The Arundelian marbles, in their perfect state, contained a chronological detail of the principal events of Greece during a period of 1318 years, beginning with Cecrops, before Christ 1582 years, and ending with the archonship of Diognetus, before Christ 264. But the chronicle of the last 90 years is lost; so that the part now remaining ends at the archonship of Diotimus, 354 years before the birth of Christ: and in this fragment the infcription is at prefent fo much corroded and effaced, that the fenfe can only be discovered by very learned and industrious antiquaries; or, more properly speaking, supplied by their conjectures.

This chronicle, and many other relicks of antiquity, real or pretended, were purchased in Asia Minor, in Greece, or in the islands of the Archipelago, by MrWilliam Petty, who in the year 1624 was fent by Thomas earl of Arundel for the purpose of making such collections for him in the east. They were brought into England about the beginning of the year 1619, and placed in the gardens belonging to Arundel house in London.

Soon after their arrival they excited a general curiofity, and were viewed by many inquifitive and learned men; among others by Sir Robert Cotton, who prevailed upon Selden to employ his abilities in explaining the Greek inscriptions. Selden and two of his friends, Patrick Young, or, as he flyled himself in Latin, Patricius Junius, and Richard James, immediately com-menced their operations, by cleaning and examining the marble containing the Smyrnean and Magnefian league, and afterwards proceeded to the Parian chronicle. The following year Selden published a fmallvolume in quarto, including about 39 infcriptions copied from the marbles.

In the turbulent reign of Charles I. and the subsequent usurpation, Arundel house was often deserted by the illustrious owners; and, in their absence, some of the marbles were defaced and broken, and others either stoken or used for the ordinary purposes of architecture. The chronological marble, in particular, was unfortu-nately broken and defaced. The upper part, containing 31 epochas, is faid to have been worked up in repairing a chimney in Arundel house.

In the year 1667, the Hon. Henry Howard, after-

Arunde- wards duke of Norfolk, the grandion of the first collector, presented these supposed remains of antiquity to the university of Oxford.

Seldon's work becoming very scarce, Bishop Fell engaged Mr Prideaux to publish a new edition of the infcriptions, which was printed at Oxford in 1676. In 1732 Mr Maittaire obliged the public with a more comprehensive view of the marbles than either of his predecessors. Lastly, Dr Chandler published a new and improved copy of the marbles in 1763, in which he corrected the miltakes of the former editors; and in some of the inscriptions, particularly that of the Parian chronicle, supplied the lacung by many inge-

nious conjectures.

The Arundelian marbles have generally been regarded as a curious monument of antiquity. They were, however, discovered in some instances to be inconsistent with the most authentic historical accounts; Sir Isaac Newton and several other modern philosophers paid little or no regard to them; and of late their ab-folute authenticity has been feverely questioned in an express differtation upon the subject, entitled The Parian Chronicle. In this differtation much ingenuity as well as judgment and a great extent of ancient learning are displayed. His doubts, the author observes,

arise from the following considerations.

I. "The characters have no certain or unequivocal marks of antiquity." The II and Z, which frequently occur in the form supposed to be the most ancient (viz. the perpendicular line of the P on the right hand only half as long as that on the left, and the Z in the form of a proftrate m), are fo well known, that any modern fabricator of a Greek infeription, which he intends to impose upon the world as a relick of antiquity, would most probably use them in preserence to the more common and ordinary forms. But the letters in the Parian chronicle have no appearance of antiquity except this very equivocal one. They do not in the leaft relemble the Sigean, the Nemean or the Delian inferiptions, which are supposed to be of a more ancient date. They differ in many respects from the letters on the Marmor Sandvicenfe, which, according to the learned editor of that infcription, was engraved in the year before Christ 374. They bear no fort of resemblance to the characters on the Farnesian pillars, to those of the Alexandrian manuscript, or others of a later date. They feem, continues our author, to refemble perhaps more than any other the letters of the alphabet taken by Montfaucon from the Marmor Cyzicenum at Venice. They are plain and simple in their form, and such as an ordinary stonecutter of the prefent age would probably make, if he were employed to engrave a Greek infeription according to the alphabet now in use. The small letters intermixed among the larger have, in the opinion of our author, an air of affectation and artifice, rather than genu.ne antiquity; and he is perfuaded, that the antiquity of an inscription can never be proved by the mere form of the letters, because the most ancient characters may be as easily counterseited as those which compose our present alphabets.

That the learned reader may form a competent idea of the characters in the Parian chronicle, the author has compared them with those of other inscriptions, and given what is usually termed a fue simile.

In regard to several archaisms, as they are called, in Arundens this chronicle, and which our author specifies, he contends, that no conclusion can be drawn from them in favour of its antiquity. What reason could there be, he alks, for introducing these into the Parian chronicle? We do not usually find them in Greck writers of the same age, or even in those of the most early date. The reign of Ptolemy Philadelphus, with the 21st year of which the date of the chronicle coincides, was not an age of rude antiquity with respect to the Greek language; being only 130 years after the time of Xcnophon and Plato, when the Greek was spoken and written in its utmost purity and elegance: and we can scarcely suppose, that even a stonecutter, in that refined age, would have been permitted to difgrace a fuperb and learned monument with such barbarisms as occur in the chronicle. The archaifms, however, he remarks, are not uniformly observed in this inscription. He adduces fix instances of deviation; and adds, he is almost tempted to suspect, that su Hage, su Magaden, and other pretended archaifms, are owing to a mere affectation of antiquity, or to a corrupted dialect and pronunciation in later ages. Those archaisms, our author acknowledges, appear on other marbles: but he thinks, that, for that very reason, they would naturally be adopted by the fabricator of a supposititious inscription; and the authenticity of those inscriptions in which they appear must be established before they can be urged in opposition to the present argument.

II. " It is not probable that the chronicle was engraved for private ufe."-Our author thinks it an impossible supposition that such an expensive and cumberfome work could have been executed by a private citizen, either for his own amusement, or for the benefit of his fellow citizens. In the first place, a long infeription could not be engraved in marble without fuch an expence as few learned Greeks were able to afford. Or, if its author, by an uncommon felicity, was able to creet fuch a literary monument, the scheme would have been useless and imprudent; as all the contents of the infcription might have been published more commodiously and effectually by the common mode of

writing in use at that time.

A variety of arguments is adduced, illustrating the fuperiority of a manuscript to such an inscription as the chronicle, in a number of respects; and enforcing the improbability of its having ever been executed, either for public or private use. Much evidence from ancient history is likewise produced in support of the affertion, that the common mode of writing, in the reign of Ptolemy Philadelphus, was not on stones. It is not, however, necessary to prove, by the testimony of ancient authors, that books were written on parchment, or paper made of the Egyptian papyrus, or any fuch materials, before the date of the Parian chronicle. This is fufficiently evinced by the very exillence of the writings of Moles, David, Solomon, and the Jewish prophets; the works of Homer, Hefiod, Anacreon, Pindar, Æschylus, Sophocles, Euripides, Herodotus, Hippocrates, Aristophanes, Thucydides, Xenophon, Plato, Demosthenes, Aristotle, &c.: And it is still more incontestably proved by the libraries which were collected in preceding ages, or about that time; fuch as those of Polycrates in Samos, Pulifratus and Euclides at Athens, Nicocrates in Cyprus, Euripides the poet,

1. 14 Maria . 18 Aristotle the philosopher, Clearchus at Heraclea Pontica, and the most extensive and magnificent library of Ptolemy Philadelphus in Egypt. founded in or before the year 284, which in his time is faid to have contain-

ed 100,000 volumes, and to have been enlarged by his fuccessors to the amount of almost 600,000. Not long afterwards a library was founded at Pergamus by Attalus and Lumenes, which, according to Plutarch contained 200,000. These are clear and decisive proofs that the common mode of writing in the time of Ptolemy Philadelphus was not on flones.

III. "The chronicle does not appear to have been

engraved by public authority."

1. The first argument in support of this opinion is, that infcriptions of that kind usually begin with a particular form; as, H BOYAH KAI O ΔΗΜΟΣ, 'The fenate and the people;' or thus, EAOEEN THI BOYAHI KAI TOI ΔΗΜΩΙ, 'It pleased the senate and the people, &c.' But the Parian chronicle begins in the manner of a private man, speaking of his own performance in the first person singular. This argument, our author remarks, cannot be much affected by observing, that the beginning of the inscription is obliterated; for it is necessarily implied by the words now remaining.

2. The facts and dates, which are mentioned in this chronicle, do not appear to have been extracted from any public records, or calculated to answer the purpose of authentic documents; as many eminent princes and magistrates are passed over without notice; in several instances, the transactions of whole centuries are omitted; and the facts, chiefly specified, are not

matters of general or national importance.

3. The Parian inscription is such a one as we can hardly suppose the magistrates or the people of Paros would have ordered to be engraved. Stately sepulchres, pillars, triumphal arches, and the like, were erected to perpetuate the glory of connent men. The remembrance of events in which nations were interested, the fuccession of princes, &c. were preserved in the same manner. Leagues, decrees, and laws, were likewise engraved on marble or brafs, and fixed to a pillar, the walls of a temple, or other public buildings; because fuch inferiptions were defigned for the infpection of the people, as they effentially concerned their conduct, Their property, their liberty, or their lives. But, our author asks, for whom could the chronicle of Paros be intended? It contains no encomiums on any of the patriots, the heroes, or the demigods of the country, no decrees of the magistrates, no public records, no laws of flate. On the contrary, it is a work of mere fpeculation and learning, in which the inhabitants of that island, especially the common people, had not the least interest or concern.

These words at the beginning, nexts res an Ilnew, would naturally lead us to suppose, that the inscription related to Paros. And, if so, it would have been nateral for the author to have mentioned fome of the most important occurences in the history of that island. But, fays this acute and learned critic, what scheme does our thronologer purfue on this occasion? Does he record reserves and revolutions of his own country?

Does linearing any of the battles, fieges, and treaties.

Parians? any of their public inflitutions? any of their poets, patriots, or warriors? Does he mention Architetta, who was honoured by his countrymen,

and diffinguished as a poet in a general affembly of the Arunda Greeks?-Not a syllable on any of these subjects! On the contrary, he rambles from place to place, and re-' cords the transactions of Athens, Corinth, Macedon, Lydia, Crete, Cyprus, Sicily, Peifia, and other foreign countries with which Paros had no connexion.

"西"版"以

In this view the infcription seems to have been as impertinent in the island of Paros, as a marble monument would be in this country, recording the antiquities of France or Spain; or one in Jamaica recording the revolutions of England. But upon supposition that the infeription is a forgery, it is easy to account for this extraordinary circumstance. A few chronological occurrences in the ancient history of Paros would not have been fo interesting to the generality of readers, or so valuable in the estimation of every lover of antiquities, or, in short, so profitable to the compiler,

as a general fystem of Grecian chronology.

IV. "The Greek and Roman writers, for a long time after the date of this work, complain that they had no chronological account of the affairs of ancient Greece." This polition is confirmed by the testimony of Julias Africanus, Justin Martyr, Plutarch, Josephus, Varro, Diodorus Siculus, and others; and the following feries of interrogatories is subjoined: 'Thucydides, I know, lived 140 years before the chronicle is said to have been written; but if Thucydides, as well as other writers, complained that there was nothing but uncertainty in the earlier period of Grecian history, from whence can we suppose the author of this inscription collected fuch a clear, determinate, and comprehensive fystem of chronology? If he had any sources of information, which were unknown to succeeding writers, how happens it, that they should all of them overlook this most considerable, most exact, most creditable author? Why did they omit this ancient account of their early ages? Why did they not copy his most memorable epochas? Why did they not produce his authority? or at least, why did they not mention his opinion? Surely nothing, to all appearance, could be more elaborate, more important, or of higher authority, than a chronological table, which was thought worthy of

being engraved on marble.
V. "The chronicle is not once mentioned by any writer of antiquity. This indeed appears a firong argument against its authenticity. Apollodorus, an Athenian, the disciple of Aristarchus the grammarian, and Panætius the philosopher, wrote a genealogical and historical work on the early ages of Greece; but, though composed 120 years after the date of the Parian chronicle, it does not contain the smallest traces of a fystematical chronology. It is remarkable too that the chronicle of Apollodorus is quoted by Diodo-, rus, Siculus, Strabo, Plutarch, A. Gellius, Lucian, and many other writers of antiquity; while the Parian. chronicle, which comprehends a more extensive period, is entirely unnoticed. It contains, however, fuch wonderful discoveries in ancient history, that if it had existed 264 years before the Christian era, it must have excited a general attention, and been referred to as an authority by writers of succeeding times. But we do not find, in any author of antiquity, either poet or historian, geographer or chronologer, mythologist or scholiast, the most distant allusion to the Parian chronicle; though it was such a common practice among Arunde- the ancients to mention the works of their predeceffors, that in many books we find references and allufions to three, four, five, fix, or feven hundred different authors of every denomination.

VI. " Some of the facts mentioned in the chronicle feem to have been taken from writers of a later date." Our inquirer collates feveral passages in the Parian chronicle with parallel passages in Greek authors, to evince that there is, in the former, an appearance of imitation, or a stronger resemblance than such as may be supposed to arise from accident; that there are likewife fome improbabilities attending the account of Deucalion, as related in the Parian chronicle; and that the names of fix, and, if the lacunæ are properly supplied, the names of 12 cities appear to have been engraved on the marble, exactly as we find them in Æhan's Various History. But there is not, our author observes, any imaginable reason for this particular arrangement. It does not correspond with the time of their foundation, with their fituation in Ionia, with their relative importance, or with the order in which they are placed by other eminent historians. The argument by which our author endeavours to prove that the Parian chronicle has, in this inflance, copied Ælian's Various History, seems decisive of the ract. He obferves, that fix names may be transposed 720 different ways; and that 12 names admit of 479,001,600 different transpositions. Supposing then, that there is no particular reason for one arrangement rather than another, it will follow, that the chance of two authors, placing them in the fame order, is, in the former case, as I to 720; and in the latter as I to 479,001,600. It is therefore, fays he, utterly improbable, that their names would have been placed in this order on the marble, if the author of the inscription had not tranferibed them from the historian."

It may indeed be urged, with regard to this fimilarity of arrangement in the Parian chronicle and Ælian's Various History, that the inference might be the very inverse of that which is specified by our author. But that Ælian should have seen the Parian chronicle, without once mentioning it; or that he should have exactly copied a list of towns, arranged neither according to chronological or topographical order; is indeed a supposition equally improbable with the other.

VII. " Parachronilms appear in some of the epochas, which we can scarcely suppose a Greek chronologer in the 120th Olympiad would be liable to commit." After specifying these, our inquirer asks, Would a writer of reputation and learning, in one of the most polished and enlightened eras of ancient Greece, commit fuch millakes in opposition to the positive attestations of the most accurate historians, in events of public notoriety? Would a private citizen, or a magnifrate of Paros, order a crude and inaccurate series of epochas to be engraved, at a great expence, and transmitted to posterity on a marble monument? It is hardly probable.

VIII. " The history of the discovery of the Parian chronicle is obscure and unsatisfactory." Our author observes, that it is attended with some suspicious circumstances, and without any of those clear and unequivocal evidences which always discriminate truth from falsehood. There are no data in the inscription by which to discover the place where the marble was erected. The place likewise where it was found is Arundon not afcertained; though the generality of writers who have had occasion to mention it have supposed that it was found in the island of Paros. If it was crected at Smyrna, as fome imagine, our author alks for what purpose does the writer mention Astyanax the archon of Paros, and not one circumstance relative to Smyrna? If, adds he, it was erected at Paros, why does he not mention more archons of that city than one? Or how shall we account for his profound silence with respect to all the events and revolutions which must have happened in that island, and have been infinitely more interesting to the natives than the transactions of any foreign country?

The train of circumstances by which the Parian chronicle came into the possession of Mr Petty, whom Lord Arundel had fent into the east for the purpose of collecting antiquities, as well as the subsequent conduct of Peirele its former owner, affords our author a strong prefumption, that "the inscription was actually fabricated, with the view of obtaining for it a high price, upon the pretence that it was a relick of great antiquity. It is certain, that there is fomething myflerious in the conduct of the full oftenfible proprietors. These marbles had been totally unknown, or unnoticed, for almost 1900 years, and at last they are dug out of the ground—no body can tell us when or where !"

IX. "The literary world has been frequently imposed upon by spurious books and inscriptions, and therefore we should be extremely cautious with regard to what we acceive under the venerable name of antiquity." This proposition is illustrated by a great variety of examples, and very properly exposes the forgenes which have difgraced the republic of letters in different ages: and although one of the more recent ones cited, namely Offian's poems, be a point very far indeed from being effablished, yet that deceptions of this kind have been practifed is an unquestionable fact.

In endeavouring towards the end of his differtation, to investigate the time of the supposed forgery, he obferves, that the 16th century, and the prior part of the 17th, produced a multitude of grammarians, critics, and commentators, deeply verfed in Grecian literature, and amply qualified for the compilation of fuch a chronological system as that of the Arundelian marbles. Above all, the science of chronology was particularly studied and invelligated about that time: " Nunc fervet chronologia," fays Scaliger in the year 1605, " omnes hoc ferrum excalfaciunt." Cafaubon treats those persons with contempt who were unacquainted with the improvements which had been made in that department of learning after the revival of letters. Innumerable fystems of chronology had been published before the year 1625; from which it was easy to extract a feries of memorable events, and give the compilation a Grecian dress. "The avidity," fays our author, "with which all relicks of antiquity were then collected, and the high price at which they were purchased, were sufficient inducements to any one, whose avarice or whose necessity was stronger than his integrity, to engrave his labours on marble, and transmit them to Smyrna, as a commodious emporium for fuch

The precise period of the fabrication, however, must

mide. Till be reckoned apocryphal and uncertain. The fire of lifty guiness, which Peirele gave to the Supposed . fabricator, was inadequate to fuch a laborious and expensive work. Upon the whole, perhaps, it would be too halty to pronounce decifively that this famous chronicle, so long respected, is an imposition upon the public. It may, however, be fafely affirmed, that the fuspicions against it are extremely strong, and the objections already cited of a nature very difficult to be removed. No attempts have yet been made with this view: But under some suture article, as Chronology, MARBLES, or PARIAN Chroticle, we may possibly have an opportunity of refuming the subject with additional information.

> ARUNDO, the REED: a genus of the digynia order, belonging to the triandria class of plants; and in the natural method ranking under the 4th order, Gramina. The calyx confifts of two valves, and the flofcules are thick and downy.

Species and properties. 1. The phragmitis, or common marsh reed, grows by the sides of rivers and in standing waters. 2. The debax, or manured reed, is as native of warm countries, but will bear the cold of our moderate winters in the open air. It dies to the furface in autumn, but appears again in the spring, and, if kept supplied with water, will grow 10 or 12 feet high in one fummer. The stalks of this are brought from Spain and Portugal; and are used by the weavers, as also for making fishing rods. 3. The verticolor, or Indian variegated reed, is supposed to be a variety of the fecond, differing from it only in having variegated * See Bam-leaves. 4. The bambos, or bamboo *, is a native of the East Indice and some parts of America; where it frequently attains the height of 60 feet. The main root is long, thick, jointed, fpreads horizontally, and fends out many cylindrical woody fibres, of a whitish colour, and many feet long. From the joints of the main root spring several round jointed stalks to a prodigious height, and at about 10 or 12 feet from the ground fend out at their joints several stalks joined together at their base : these run up in the same manner as those they shoot out from. If any of these be planted with a piece of the first stalk adhering to them, they will perpetuate their species. They are armed at their joints with one or two sharp rigid spines, and furnished with oblong oval leaves, eight or nine inches long, feat-ed on short foot stalks. The slowers are produced in large panicles from the joint of the stalks, placed three in a parcel close to their receptacles: they resemble those of the common reed, and are succeeded by seeds of the same form surrounded with down.

The young shoots are covered with a dark green bark; these when very tender are put up in vinegar, falt, garlic, and the pode of capticum, and thus afford a pickle, which is effected a valuable condiment in the Indies, and is faid greatly to promote the appetite and affift digestion (see Achtar). The stalks in their young thate are almost folid, and contain a milky juice : this is of a fweet nature; and as the stalks advance in age, they become hollow, except at the joints, where they are Ropped by a woody membrane, upon which this liquor lodges and concretes into a substance called Tabanir or fugar of Mombu, which was held in such esteem by the ancients, in some particular disorders, that it was equal in value to its weight in filver. The

ald finike grow to five or fix inches diameter, are then Arendo. of a faining yellow colour, and are so hard and durable Arusai. that they are used in buildings, and for making all' forts of household furniture. These when bored through the membranes at their joints, are converted into water pipes. They serve also to make the slicks and poles with which the flaves or other perfors carry those forts of litters which are called palanquins, and are fo common and convenient in all the east. The smaller stalks are used for walking slicks. The inhabitants of Otaheite make slutes of them, about a foot long, with two holes only, which they stop with the first finger of the left hand and the middle one of the right, and they blow through their nostrils. 5. The arborea, with a tree-like stalk, differs from the former only in having narrower leaves. 6. The orientalis is what the Turks use as writing pens; it grows in a valley near Mount Athos, as also on the banks of the river Jordan. None of these plants are at present to be found in Britain.

Culture. As all these plants grow naturally in low marshy lands, they must be supplied with plenty of water. The second kind requires little care; the third is more delicate, and requires to be kept in pots. The fourth, fifth, and fixth forts must be preferred in stoves. They are to be planted in tubs filled with rich earth, and plentifully supplied with water. When the tubs decay they may be suffered to grow into the tan, which will encourage them to grow to a larger fize; but care must be taken, when the bed is refreshed with new tan, to leave a sufficient quantity of old tan about the roots of the plants; for if they are too much bared and the new tan laid near them, when that heats it will fcorch their roots, fo that the plants are fometimes destroyed by it.

nes destroyed by it. Arundo Sacebarifera, or Sogar cans. See Sacena-

ARUSINI camps (erroneously written Taurafini by Cluverius). plains in Lucacia, famous for the last battle fought between the Romans and Pyrrhus. That prince being at Tarentum, and hearing that the two new confule Curius Dentatus and Cornelius Lentulus had divided their forces, the one including Lucania and the other Samnium; he likewife divided a chofen detachment of his army into two bodies, marching with his Epirots against Dentatus, in hopes of surprising him in his camp near Beneventum. But the conful having notice of his approach, marched out of his intrenchments with a firong detachment of legionaries to meet him, repulsed his vanguard, put many of the Epirots to the fword, and took some of their elephants. Curius, encouraged by this success, marched into the Arufian fields, and drew up his army in a plain, which was wide enough for his troops, but too narrow for the Epirot phalanx to act with its full effect. But the king's eagerness to try his strength and skill with so renowned a commander, stimulated him to engage at that great disadvantage. Upon the first fignal the action began; and one of the king's wings giving way, victory feemed to incline to the Romans. But that wing where the king fought in person repulsed the enemy and drove them to their intrenchments. This advantage was in great part owing to the elephants; a circumstance which Curius perceiving, commanded a body of referve, which he had posted near

Aruspices the camp, to advance and attack those animals with burning torches; which frightened and annoyed them Arzilla to fuch a degree, that they wheeled about, broke into the phalanx, and put that body into the utmost diforder. The Romans taking advantage of this confusion, charged with fuch fury that the enemy were entirely broken and defeated. Pyrrhus retired to Tarentum, attended only by a small body of horse, leaving the Romans in full possession of his camp; which they so much admired, that they made it a model which they followed ever after.

AEZ

ARUSPICES, or HARUSPICES, in Roman antiquity, an order of prietts who pretended to foretel future events by inspecting the entrails of victims killed in facilitie; they were also consulted on occasion of portents and produgies. The haruspices were always chosen from the best families; and as their employment was of the same nature as that of the augurs, they were as much bonoured. Their college, as well as those of the other religious orders, had its particular regulters and records.

ARX, in the ancient military art, a town, fort, or

castle, for defence of a place.

The arx in ancient Rome was a distinct edifice from the capitol, though some have confounded the two. According to Ryckius, the arx, properly speaking, was a place on the highest part of the Capitoline mount, stronger and better fortified than the rest, with towers and planated walls: in which was also the temple of Jupiter Capitolinus.

Arx also denoted a consecrated place on the Palatine mount, where the augurs publicly performed their office. Some will have the arx to have been the augural temple; but Varro expressly distinguishes be-

tween the two.

As x was particularly used for a public place in Rome, fet apart for the operations of the augurs. In which fense ark amounts to the same with what is otherwise called auguraculum and auguratorium, and in the camp augurale. Out of this arx it was that the feciales, or heralds, gathered the grass used in the ce-

remony of making leagues and treaties.

Aux Britannica, a citadel of Batavia, whose foundation is feen at low water, near the old mouth of the middle Rhine: some imagine it the pharos or high tower of Caligula, as Suctonius calls it; a monument of Caligula's than conquest of Britain. Others, that it was built by Drusus, with an altar afterwards by Claudius, on his expedition into Britain. But the usual passage was from Gessoriacum; and Suctonius expressly says, Claudius passed over thence. The ancient name of this citadel, now covered by the fea, is nowhere expressed: Now commonly called 't Huis Britten, or Brittenburg; that is, Arn Britannica; but from what authority does not appear.

ARYTENOIDES, in anatomy, the name of two vartilages which, together with others, constitute the head of the larynx. It is also applied to some muscles

of the larynx.

ARYTHMUS, in medicine, the want of a just modulation in the pulse. It is opposed to eurythymus, a

pulse modulated agreeably to nature.

ARZILLA, a very ancient maritime town of Africa, in the kingdom of Fez, about five leagues from Vos. II. Part I.

Tangiers. It is built at the mouth of a river, and inhabited by Moore and Jews, who carry on no trade. It was formerly a Roman colony; afterwards fell under the government of the Goths; and was next taken by the Mahometans. Alphonfo of Portugal, furnamed the African, took it by affault in 1471, and brought away the presumptive heir of the crown. After that prince came to the throne, he belieged it, in 1508, with 100,000 men; but was obliged to abandon the undertaking. However, at length the Portuguese forsook it of their own accord. W. Long. 5. 30. N. Lat. 35. 30.

AS, in antiquity, a particular weight, confilling of 12 ounces; being the lame with libra, or the Roman The word is derived from the Greek au, which in the Doric dialect is used for us, out, q. d. an entire thing; though others will have it named as

quali es, because made of brass.

As was also the name of a Roman coin, which was of different weights and different matter in different ages of the commonwealth.—Under Numa Pompilius, according to Eusebius, the Roman money was either of wood, leather, or shells. In the time of Tullus Hostilius, it was of brass; and called as, libra, libella, or pondo, because actually weighing a pound or 12 ounces. Four hundred and twenty years after, the first Punic war having exhausted the treasury, they reduced the as to two ounces. In the second Punic war, Hannibal preffing very hard upon them, they reduced the as to half its weight, viz. to one ounce. And, laftly, by the Papirian law, they took away half an conce more, and confequently reduced the as to the diminutive weight of half an ounce; and it is generally thought that it continued the fame during the commonwealth, and even till the reign of Vespasian. The as therefore was of four different weights in the coinmonwealth. Its original flamp was that of a sheep, ox, or fow: but from the time of the emperors, it had on one fide a Janus with two faces, and on the reverse the rostrum or prow of a ship.

As was also used to denote any integer or whole. Whence the English word ace. Thus as figurated the whole inheritance; whence heres ex affe, the heir to

the whole estate.

ASA, king of Judah, succeeded his father Abriam, He pulled down the altars erected to idols, restored the worship of the true God, and, with the affishance of Benhadad king of Syria, took feveral towns from the king of Ifrael. He died 917 years before the Chuiftian era, and was succeeded by Jehoshaphat.

Asa, among naturalists. The writers of the later

ages have formed this word afa from the lafar of the ancients, and attributed it to a gum very different from that anciently known by the name they have

thus corrupted.

The afa of the ancients was an odoriferous and fragrant gum; and the afa of the after ages had so little title to this epithet, that they distinguished it by one, expressing its being of an offeasive or slinking smell. The Arabian writers, according to this diffinction, describe two kinds of asa, the one stinking, the other aromatic; and the modern Greeks preserved the name afa, or lafar, to the stinking gum the Latins called by that name, but added a diffinctive epithet to express its smell, and called it fcardolafarum.

Afbestos.

As or Assa, in the materia medica, a name given to two very different substances, called afa-dulcie and afa-fætida.

As A Dulcis is the same with BENZOIN.

AsA-Fatida is the concrete juice of a large umbelliferous plant growing in several parts of Asia; the properties of which are described under the article Fr-RULA.

ASAPH (St), a city in Flintshire, with a bishop's fee; on which account principally it deserves notice, being in itself but a poor place. As a bishoprick, it is of great antiquity, and was founded about the year 560, by Kentigern, a Scotsman, bishop of Glasgow. He began the church on the banks of the river Elwy, whence it is called by the Welsh Land Elwy, and in Latin Elwensis. Kentigern returning into Scotland, left a holy man his successor, St Asaph. Who was his fuccessor is uncertain, as there are no records that mention it; and it feems rather probable that the religious fettled here had been necessitated to remove to fome more peaceable abode, as the country was frequently the feat of war between the English and the Welsh. This see was formerly a very wealthy one; but its revenues were greatly leffened by the profusion of Bishop Parfew, who alienated much of the lands belonging to this bishoprick.

This diocese doth not contain any one whole county; but confifts of part of Denbigh, Flint (where its church is), Montgomery, and Merioneth shires, and a small part of Shropshire; wherein are 121 parishes, and 131 churches and chapels, most of which are in the immediate patronage of the bishop. This fee hath but one archdeaconry, viz. that of St Afaph, which is united to the bishoprick, for the better maintenance thereof. This see is valued in the king's books at 1871. 118. 6d. but computed to be worth annually 1500l. The tenth of the clergy comes to 1861. 19s. 61d. To this cathedral belongs a bishop, a dean, archdeacon, chan-

cellor, &c.

ASAPPES, or AZAPES, an order of foldiers in the Turkish army, whom they always expose to the first shock of the enemy: to the end that the enemy being thus fatigued, and their fwords blunted, the spahis and januzaries may fall on and find an easy conquest. The word is derived from the Turkish faph, which signifies rank, from whence they have formed asphaph, " to range in battle." The asappes are said to be held of fo little value, that they frequently ferve as bridges for the cavalry to pass over in bad roads, and as fascines to fill up the ditches of places besieged. They travel on foot, and have no pay but the plunder they can get from the enemy.

ASAR-ADDON, or ESAR-HADDON, the son of Sennacherib, succeeded his father about 712 years before the Christian era, and united the kingdoms of Nineveh and Babylon. He rendered himself mafter of Syria; fent a colony to Samaria; and his generals took King Marties, and caried him loaded with chains to Babylon. Afar-Addon died after a reign of 12 years.

ASARINA. See Carlons.

ASAROTA, assesses, from a and suice, I freesp, a kind of parted pavements in use before the invention of most with. The most celebrated was that at Persentification of the second of crimes the floor had not been swept after dinner, whence, according to Pliny, the denomination. Perrault supposes them to have been a black kind of pavements of a spongy matter.

ASARUM, ASARABACCA: A genus of the monogynia order, belonging to the dodecandria class of plants. The calyx is trifid or quadrifid, and rests on the germen; there is no corolla; the capfule is leathery and crowned .- The species are three; the Europeum, the Canadense, and Virginicum. The first species grows naturally in some parts of England. It hath thick fleshy jointed roots; the leaves grow fingly upon short footstalks, which arise immediately from the root: the flowers grow upon very short footstalks close to the ground, so are hid under the leaves. They have a bell-shaped empalement, of a worn-out purple colour, which is cut in three at the top, where it turns backward. It delights in a moist shady place, and may be propagated by parting the roots in autumn. The two other species have no remarkable properties.

Medicinal Uses. The dried roots of this plant have been generally brought from the Levant; those of our own growth being supposed weaker. Both the roots and leaves have a naufeous, bitter, acrimonious, hot tafte; their fmell is strong, and not very disagreeable. Given in substance from half a dram to a dram, they evacuate powerfully both upwards and downwards. It is faid, that tinctures made in spirituous menstrua, posfels both the emetic and cathartic virtues of the plant; that the extract obtained by inspissating these tinctures, acts only by vomit, and with great mildness; that an infusion in water proves cathartic, rarely emetic; that aqueous decoctions made by long boiling, and the watery extract, have no purgative or emetic quality, but prove notable diaphoretics, diuretics, and emmena-

gogues.
The principal use of this plant among us is as a sternutatory. The root of afarum is perhaps the strongest of all the vegetable errhines, white hellebore itself not excepted. Snuffed up the nofe, in the quantity of a grain or two, it occasions a large evacuation of mucus, and railes a plentiful spitting. The leaves are considerably milder, and may be used to the quantity of three, four, or five grains. Geoffroy relates, that after fnuffing up a dofe of this errhine at night, he has frequently observed the discharge from the nose to continue for three days together; and that he has known a paralysis of the mouth and tongue cured by one dose. He recommends this medicine in stubborn disorders of the head proceeding from viscid tenacious matter, in palfies, and in foporific diffempers. The leaves are the principal ingredient in the pulvis sternutatorius, or pulvis afari compositus, as'it is now called, of the shops.

ASBAMEA, a fountain of Cappadocia, near Tyana, facred to Jupiter, and to an oath. Though this fountain bubbled up, as in a state of boiling, yet its water was cold; and never ran over, but fell back a-

gain: (Philostratus, Ammian).

ASBESTOS, a fort of native fossil stone, which may be split into threads and filaments, from one inch to ten inches in length, very fine, brittle, yet fomewhat tractable, filky, and of a grayish colour, not unlike tale of Venice. It is almost insipid to the taste. indiffoluble in water, and endued with the wonderful property of remaining unconfumed in the fire, which only whitens it. There are some forts of asbestos

whofe

Asbestor whose silaments are rigid and brittle; others more

The industry of mankind has found a method of working this untoward mineral, and employing it in divers manufactures, chiefly cloth and paper. manufacture is undoubtedly difficult enough. Pliny calls the asbestos inventu rarum, textu difficilimum. Wormius affures us, that the method of making cloth of asbestos is now entirely unknown. And indeed one would fearce imagine the thing practicable, without the mixture of some other pliant matter, as wool, hemp, or flax, along with the asbellos, the filaments of this latter appearing too coarse and brittle to make any tolerable fine work. However this be, Bapt, Porta affures us, that in his time the spinning of asbestos was a thing known to everybody at Venice. Sig. Caftagnatta, superintendant of some mines in Italy, is faid to have carried the manufacture to fuch perfection, that his asbestos was soft and tractable, much resembling lamb skin dressed white: he could thicken and thin it at pleasure; and thus either make it into a very white

ikin or a very white paper.

This kind of linen cloth was chiefly efteemed by the ancients; though then better known and more common than among us, being held equally precious with the richest pearls: nor is it now of mean value, even in the country where it is most generally made, a China cover (i. e. a piece of 23 inches and three-quarters long) being worth 80 tale, i. e. 36l. 13s. 4d. Pliny fays, he himself had seen napkins thereof, which, being taken foul from the table after a feast, were thrown into the fire, and by that means were better scoured than if they had been washed in water, &c. But its principal use, according to Pliny, was for the making of shrouds for royal funerals, to wrap up the corpse, fo that the ashes might be preserved distinct from those of the wood, &c. whereof the funeral pile was composed: and the princes of Tartary, according to the accounts in the Philosophical Transactions, still use it at this day in burning their dead. Some of the ancients are laid to have made themselves clothes of it, particularly the Brachmans among the Indians. The wicks for their perpetual lamps, according to Dr Lifter, were also made of it; some to this day use it for the wicks of such lamps as they would not have any trouble with; because the asbestos never wasting, there is no occasion for shifting the wick. Septalla, canon of Milan, had thread, ropes, nets, and paper, made of the asbestos. A handkerchief or pattern of this linen was long fince prefented to the Royal Society, a foot long and half a foot broad. This gave two proofs of its relifting fire; though, in both experiments, it loft above three drams of its weight. When taken out red hot, it did not burn a piece of white paper on which it was laid. Mr Villette pretends that his large burning concave usually vitrifies the asbestos.

The method of preparing the incombustible paper and cloth is thus described by Ciampini: The stone is laid to foak in warm water; then opened and divided by the hands, that the earthy matter may be washed out. The ablution being feveral times repeated, the flaxlike filaments are collected and dried; and they are most conveniently spun with an addition of flax. Two or three filaments of the afbellos are easily twifted along with the flaxen thread, if the operator's fingers are kept oiled. The cloth also, when woven, is Af along best preferred by oil from breaking or wasting. On expolure to the fire, the flax and the oil burn out, and Meridantel the cloth remains pure and white. Probably from the diffipation of some extraneous matter of this kind proceeded the diminution of weight in the handkerchief just recited; for pure asbestos leaves nothing. The shorter filaments which separate in washing the stone may be made into paper in the common manner.

The asbestos is found in Crete and Cyprus; in Tartary; at Namur in the Low Countries; in Thuringia among the mines; in the old Noricum; in Egypt; in the mountains of Arcadia; at Puteoli; in the illand of Corfica; in the island of Anglesev in Wales; in Aberdeenshire in Scotland; at Montauban in France;

and in Siberia.

ASCALON, an ancient city, and one of the five fatrapies or principalities of the Philistines; situated on the Mediterranean; 43 miles to the fouth-west of Jerusalem (Antonine), between Azotus to the north and Gaza to the fouth. The birth place of Herod the Great, thence furnamed Afcalonita (Stephanus). Famous for its scallions, which take name from this town (Strabo, Pliny). Now Scalona. E. Long. 34. 30. Lat. 31. 30.

ASCANIUS, the fon of Æneas and Creufa, fucceeded his father in the kingdom of the Latins, and defeated Mezentius king of the Tuscans, who had refused to conclude a peace with him. At length he founded Alba Longa; and died about 1139 years before the

Christian era, after a reign of 38 years.

ASCARIS, in zoology, a genus of infects belonging to the order of vermes intestina. The body of the afcatis is cylindrical, filiform, and tapers at both ends. The species are two, viz. 1. The vermicularis, with plate LIV. faint annular rugæ, and the mouth traverse, is about a quarter of an inch long, and thicker at one end than the other. It is found in boggy places, in the roots of putrid plants, and very frequently in the rectum of children and horses. It emaciates children greatly, and is fometimes vomited up. 2. The lumbricoides is about the fame length with the lumbricus terrestris, or common earth worm; but it wants the protuberant ring towards the middle of the body, the only mark by which they can properly be diffinguished. The body of the lumbricoides is cylindrical, and fubulated at each extremity; but the tail is fomewhat triangular. The lumbricoides'is the worm which is most commonly found in the human intestines. It is viviparous, and produces Tast numbers. For the method of expelling these two kinds of infects, see Medicine, Index.

ASCENDANT, in astrology, denotes the horoscope, or the degree of the ecliptic which rifes upon the horizon at the time of the birth of any one. This is supposed to have an influence on the person's life and fortune, by giving him a bent and propenfity to

one thing more than another.

In the celestial theme, this is also called the first house, the angle of the East or Oriental angle, and the fignificator of life .- Such a planet ruled in his afcendant: Jupiter was in his afcendant, &c. - Hence the word is also used in a moral sense, for a certain superiority which one man has over another, from fome unknown

ASCENDANTS, in law, are opposed to descendants

Accending, in fuccession; i. e. when a father succeeded his son, or assertion an uncle his nephew, &c. heritage is said to ascend, or go to ascendants.

ASCENDING, in astronomy, is said of such stars as are rising above the horizon in any parallel of the

ASCENDING Latitude, is the latitude of a planet when

going towards the north pole.

ASCENDING Node, is that point of a planet's orbit, wherein it passes the ecliptic, to proceed northward. This is otherwise called the northern node, and represented by this character &.

ASCENDING Vessels, in anatomy, those which carry the blood upwards; as the aorta ascendens. See Ana-

TOMY, Nº 123.

ASCENSION, in aftronomy, is either right or oblique. Right afcension of the sun, or a star, is that degree of the equinoctial, counted from the beginning of Aries, which rises with the sun or star in a right sphere. Oblique ascension is an arch of the equator intercepted between the first point of Aries and that point of the equator which rises together with a star in an oblique sphere.

Ascension Day, a festival of the Christian church, held ten days before Whitsuntide, in memory of our Savious's ascension into heaven after his resurrection.

Ascension Island, a barren island on the coast of Africa, lying in W. Long. 17. 20. S. Lat. 7. 5. The following account is given of it by Mr Forster. "This island was first discovered in 1501, by toao de Nova Galego, a Portuguese navigator, who named it Ilba' de Noffet Senhora de Conceição. The fame admiral on his return to Portugal in 1502, discovered the island of St Helena, which obtained that name from the day of the discovery. Ascension was seen a second time by Alfonso d'Albuquerque on his voyage to India in 1503, and then received the name it now bears; but was already at that time in the same desolate condition as at present. We sent several parties on shore, who passed the night on the watch for turtles, which came to lay their eggs on the fandy shores. dreatmels of this island fur passed all the horrors of Easter Island and Tierra del Fuego, even without the affistance of fnow. It was a rumous heap of rocks, many of which, as far as we could differn from the ship, feemed to be totally changed by the fire of a volcano. Nearly in the centre of the island rifes a broad white mountain of great height, on which we difference fome verdure by the help of our glasses, from whence it has obtained the name of Green Mountain.

"We landed early in the morning among some rocks, the surf being always immensely high on the great beach; which consists of minute shell-sand, chiefly of a snowy white, very deep, dry, and intolerable to the eyes when the sun shines. We ascended among heaps of black cavernous stone, which perfectly refembles the most common lavas of Vesuvius and Iceland, and of which the broken pieces looked as if they had been accumulated by art. The lava currents couling very suddenly, may easily be imagined to produce such an effect. Having ascended about 12 or 15 yards perpendicular, we found ourselves on a great level plain of hx or eight toiles in circuit; in the different corners of which we observed a large hill of an exact conical shape, and of a reddish colour, standing perfectly insu-

lated. Part of the plain between these conic hills was Ascension. covered with great numbers of smaller hillocks, confiding of the same wild and ragged lava as that near the sea, and ringing like glass when two pieces are knocked together. The ground between the heaps of lava was covered with a black earth, on which we walked very firmly; but when these heaps did not appear, the whole was a red earth, which was fo loofe, and in fuch dry minute particles, that the wind raifed clouds of dust upon it. The conic hills consisted of a very disferent fort of laya, which was red, foft, and crumbling into earth. One of these hills stands directly in front of the bay, and has a wooden crofs on its fummit, from whence the bay is faid to take its name. Its fides are very steep, but a path near three quarters of a mile long winds round it to the fummit. After examining this remarkable country a little longer, we concluded, with a great degree of probability on our fide, That the plain on which we flood was once the crater or feat of a volcano, by the accumulation of whose cinders and pumice stones the conic hills had been gradually formed: that the currents of lava which we now faw divided into many heaps, had perhaps been gradually buried in fresh cinders and ashes; and the waters coming down from the interior mountain in the rainy feafon had fmoothened every thing in their way, and filled up by degrees the cavity of the crater. The rocky black lava was the residence of numberless men-of-war birds and hoobies, which fat on their eggs, and fuffered us to come close to them.

"About eight in the evening, it being then quite dark, a small vessel came into the bay, and anchored directly within us. Captain Cook having hailed her repeatedly, received in answer that she was the Lucretia, a New York sloop, which had been at Sierra Leon, and was now come to catch turtles, in order to fell them at the windward islands of the West Indies. A licutenant was fent on board, who learned from the master, that he had taken our ship to be a French Indiaman, and was very defirous of trading with English India ships, in which he was disappointed by the company's regulations. He dined with our officers the next day, but on the 31st at day-break left the island. On the 30th in the morning, we landed a second time; and, croffing the plain, arrived at a prodigious lava current, interfected by many channels from fix to eight yards deep, which bore strong marks of being worn by vast torrents of water, but were at present perfectly dry, the fun being in the northern hemisphere. In these gullies we found a small quantity of soil consisting of a black volcanic earth, mixed with some whitish particles gritty to the touch. Here we saw some small bunches of pursiane, and a species of grass (panicum fanguineum) which found sufficient nutriment in the dry foil. Having at last, with great fatigue, climbed over this extensive and tremendous current of lava, which was much more folid than the heaps nearer to the fea, we came to the foot of the Green Mountain, which even from the ship's place in the bay we had plainly distinguished to be of a different nature from all the rest of the country. Those parts of the lava which furrounded it were covered with a prodigious quantity of purssane, and a new kind of fern (lonchites Adscenfionis), where several flocks of wild goats were feeding. The great mountain is divided in its extremities,

Ascension by various clefts, into several bodies; but in the centre they all run together, and form one broad mass of great height. 'The whole appears to confift of a gritty tophaceous lime stone, which has never been attacked by the volcano, but probably existed prior to its cruption; its sides are covered with a kind of grass, peculiar to the island, which Linnaus has named ariftida Adjeenfionis. We likewise observed several slocks of goats feeding on it; but they were all excessively shy, and ran with furprifing velocity along tremendous precipiees, where it was impossible to follow them. The master of the New York sloop acquainted us, that there is a spring of water on one part of this mountain, which falls down a great precipice, and is afterwards absorbed in the fand. I am almost persuaded, that, with a little trouble, Afcension might shortly be made fit for the residence of men. The introduction of furze (ules Europaus), and of a few other plants which thrive best in a parched foil, and are not likely to be attacked by rats or goats, would foon have the fame effect as at St Helena. The moisture attracted from the atmosphere by the high mountains in the centre of the illand, would then no longer be evaporated by the violent action of the fun, but collect into sivulets, and gradually supply the whole island. A fod of grasses would everywhere cover the surface of the ground, and annually increase the stratum of mould, till it could be planted with more useful vege-

"We returned gradually to Cross Bay, in the heat of noon, over the plain; having a space of more than five miles to traverse, where the sun burnt and blistered our faces and necks, and heated the foil to such a degree, that our feet were likewise extremely fore. About three o'clock we arrived at the water's fide; and after bathing in a small cove among a few rocks. we made the figual for a boat, and were taken on The next forenoon we made another small excursion, in company with Captain Cook, towards the Green Mountain; but we were all of us so much fatigued, that we could not reach it. We made no new observations in the course of this day, the nature of the island being dreary beyond description in its outskirts."

ASCENSIONAL DIFFERENCE, the difference between the right and oblique ascension of the same point to the furface of the sphere.

ASCENT, in a general fense, implies the motion of a body upwards, or the continual recess of a body from the earth. The Peripatetics attribute the spontaneous ascent of bodies to a principle of levity inherent in them. The moderns deny any fuch thing as spontaneous levity; and show, that whatever ascenda, does it in virtue of some external impulse or extrusion. Thus it is that smoke and other rare bodies ascend in the atmosphere; and oil, light woods, &c. in water; not by any external principle of levity, but by the fuperior gravity or tendency downwards of the parts of the medium wherein they are. The afant of light bodies in heavy mediums is produced after the fame manner as the afcent of the lighter scale of a balance. It is not that fuch scale has an internal principle whereby it immediately tends upwards; but it is impelled upwards by the preponderancy of the other feal; the excels of the weight of the one having the fame effect,

by augmenting its impetus downwards, as fo much Affont real levity in the other; by reason the tendencies mutually oppose each other, and that action and reaction Ascharaare always equal.

ASCENT of Boilies on Inclined Planes, the reader will find explained under MECHANICS; Afcent of Fluids, under Hydrostatics; and Ascent of Vapours, under the article EVAPORATION.

ASCESIS, properly denotes exercise of the body. It is formed from the verb mount, used by the ancients in speaking of the sports and combats of the athletæ.

Ascesis is also used by philosophers, to denote an exercife conducive to virtue, or to the acquiring a greater degree of virtue. This is particularly denominated the philosophical ascess, because practised chiefly by philosophers, who make a more peculiar profession of improving themselves in virtue; on the model whereof the ancient Chrislians introduced a religious Ascesis.

ASCETERIUM, in ecclesiastical writers, is frequently used for a monastery, or place set apart for the exercise of virtue and religion. The word is formed from ascessis, " exercise;" or ascetra, " one who performs exercife." Originally it fignified a place where the athletæ or gladiators performed their exercises.

ASCETIC, an ancient appellation given to fuch persons as, in the primitive times, devoted themselves more immediately to the exercises of piety and virtue, in a retired life; and particularly to prayer, abstinence and mortification. The word is derived from armin, exerceo, " I exercife." Afterwards, when the monks came in fashion, this title was bestowed upon them; especially upon such of them as lived in so-

Ascetic is also a title of several books of spiritual exercises.—As, the Ascetics, or devout exercises of St Bafil, archbishop of Cesarca in Cappadocia.

We also say the ascetic life, meaning the exercise of prayer, meditation, and mortification.

ASCHAFENBURG, a town of Germany, feated on the river Maine, in the circle of the Lower Rhine, and territory of the elector of Mentz, who has a palace there. It is memorable for being the place where the king of Great Britain took up his quarters the night before the battle of Dettingen. E. Long. 9.

35. N. Lat. 50. 14. ASCHAM (Roger), was born at Kirby-Wilke, near North Allerton in Yorkshire, in the year 1516. His father was fleward to the noble family of Scroop. Our author Roger was educated in the family of Sir Anthony Wingfield, who, about the year 1530, fent him to St John's College, Cambridge, where he was foon diffinguished for his application and abilities. He rook his degree of bachelor of arts at the age of 18, was foon after elected fellow of his college, and in 1536 proceeded mafter of aits. In 1544, he was chosen university orator; and, in 1548, was fent for to court, to inflruct the lady Elizabeth (afterwards queen) in the learned languages. In the year 1550, he attended Sir Richard Moryline, as feeretary, on his embaffy to the emperor Charles V. at whose court he continued three years, and in the mean time was appointed Latin fecretary to King Edward VI. But apon the death of that prince, he loft his preferment

hisham and all his hopes, being professedly of the reformed religion; yet, contrary to his expectations, he was foon after, by the interest of his friend Lord Paget, made Latin fecretary to the king and queen. In June 1554, he married M18 Margaret How, a lady of a good family, with whom he had a confiderable fortune. It was very remarkable of Mr Ascham, that though he was known to be a Protestant, he continued in favour not only with the ministry of those times, but with Queen Mary herfelf. Upon the accession of Queen Elizabeth, he was not only confirmed in his pult of Latin fecretary, but was conflantly employed as preceptor to her majesty in the Greek and Latin languages. He died in the year 1568, much regretted, especially by the queen, who said she would rather have lost 10,000 l. Camden and some other writers tell us, that he had a great propenfity to dice and cock fight-

ing. He certainly died poor .- He wrote,

1. Toxophilus. The schole or partitions of shooting, contayned in two bookes, written by Roger Afcham, 1544, and now newly peruled. Pleafaunt for all gentlemen and yeomen of England, &c. Lond. 1571. Whilst at the university he was fond of archery by way of exercise and amusement, for which he was cenfured; and on that account he fat down to write this book, which was dedicated to Henry VIII. who fettled a penfion of 10l. per annum on the author. It is rather whimfical; but is admirably well written and full of learning. 2. A report and difcourse, written by Roger Ascham, of the affairs and state of Germany, and the emperor Charles his court &c. 4to. a valuable curiofity. 3. The schoolmaster, first printed in 1573, 4to. Mr Upton published an edition with notes in 1711. It has uncommon merit; abounding in great good sense, as well as knowledge of ancient and modern history: it is also expresfive of the great humanity of the author, who was for making the paths of knowledge as level and pleafant as possible, and for trying every gentle method of enlarging the mind and winning the heart. 4. Latin epiffles; first published by Mr Grant 1576; have fince passed many editions: the best is that of Oxford in 1703. Much admired on account of the style, and efteemed almost the only classical work of that kind written by an Englishman. 5. Apologia contra misfam. 1577, 8vo.

ASCIBURGIUM (anc. geog.), mentioned by Tacitus, supposed to be one of the 50 citadels built on the Rhine; who adds, some imagined it was built by Ulysses. Here was a Roman camp and a garrison. To its situation on the banks of the Rhine answers a small hamlet, now called Asburg not far from Meurs, in the

duchy of Cleves.

ASCIDIA, a genus of animals belonging to the order of vermes mollusca. The body is cylindrical and fixed to a shell, rock, &c. It has two apertures; one on the fummit, the other lower, forming a fheath. There are fix species of this animal, viz. the papillosum, gelatinosum, intestinalis, quadridentata, rustica and gechinata; only one of which, viz. the ruftica *, is found in the British seas. Animals of this genus have the faculty of squirting out the water they take in. The expansion and contraction of their bodies occasion their affuming various forms.

ASCII, among geographers, an appellation given

to those inhabitants of the earth who, at certain seasons. Assira of the year have no fliadow; fuch are all the inhabitauts of the torrid zone, when the fun is vertical to them.

ASCITE, (from woxes, a leag or bottle), in antiquity, a feet or branch of Montanists, who appeared in the fecond century. They were fo called, because they introduced a kind of Bacchanals into their affemblies, who danced round a bag or skin blowed up : faying, they were those new bottles filled with new wine whereof our Saviour makes mention, Matth. ix. 17 .-They are functimes also called Ascodrogita.

ASCITES, in medicine, the dropfy of the abdo-

men. See Medicini, Indix.

ASCLEPIA, a festival of Æsculapius the god of physic, observed particularly at Epidaurus, where it was attended with a contest between the poets and muficians, whence it was likewife called lees Ayar, the facred contention.

ASCLEPIAD, in ancient poetry, a verse composed of four feet, the first of which is a sponder, the second a choriamhus, and the two last dactyls; or of four feet and a cæfura, the first a spondee, the second a dactyl, after which comes the cassura, then the two

dactyls; as, Macenas atavis edite regibus.

ASCLEPIADES, one of the most celebrated phyficians among the ancients, was a native of Prufa, in Bithynia; and practifed physic at Rome, under Pompey, 96 years before the Christian era. He was the head of a new fect; and, by making use of wine and cold water in the cure of the fick, acquired a very great reputation. He wrote several books, which are frequently mentioned by Galen, Celfus, and Pliny; but they are now loft.

ASCLEPIADES, a famous physician under Hadrian, of the same city with the former. He wrote several books concerning the composition of medicines; both

internal and external.

ASCLEPIAS, SWALLOW-WORT: A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 30th order, Conforta. The generic character is taken from five oval, concave, horn-like nectaria which are found in the flower. The

Species are 19; of which the following are the most remarkable. 1. The alba, or common swallow-wort, has a root composed of many strong fibres connected at top like those of asparague, from whence arise many stalks, in number proportional to the fize of the roots, which grow two feet high, and are very slender at the top: the leaves are placed opposite by pairs; the flowers are white, growing in umbels near the top of the stalk, from whence are fent out smaller umbels, After the flower is past, the two germens become long pointed pods, enclosing many compressed seeds lying imbricatim, which are crowned with a foft white down. It flowers in June, and the feeds ripen in September. It is a native of the fouth of France, Spain, and Italy. 2. The Syriaca, or greater Syrian doglbane, is a perennial plant, which fends up several upright stalks in the fpring, about two feet high, garnished with oval leaves growing opposite; at the top of the stalks the umbels of flowers are produced, which are of a bright purple colour, making a pretty appearance, but are not succeeded by pods in England. 3. The curraffavica, or bastard ipecacuanha, is a native of the warm parts

Asclepias of America. It rises to the height of five or fix feet, with upright stems, and smooth oblong leaves placed Afterptitile opposite. Toward the top of the branches the umbels of flowers come out, which flund erect : the petals of the flowers are of a scarlet colour, and the horny nectariums in the middle are of a bright faffron colour, which make a pretty appearance; and there is a fuccession of slowers on the same plant from June to October. The flowers are fucceeded by long taper pods, filled with feeds crowned with a foft down, which ripen late in autumn. The first two species are hardy; but the last one is tender, and therefore must be preserved in a flove.

> Medicinal Uses, &c. The root of the first species is used in medicine. It is reckoned by hotanists a species of dogsbane; from all the poisonous forts of which it may be diffinguished, by yielding a limpid juice, whilst that of the others is milky. The root has a strong smell, especially when fresh, approaching to that of valerian, or nard; the taste is at first fweetish and aromatic, but soon becomes bitterish, subacrid, and nauseous. This root is esteemed sudorific. diurctic, and emmenagogue: it is also frequently employed by the French and German physicians as an alexipharmic, and fometimes as a fuccedaneum to contrayerva, whence it has received the name of contrayerva Germanorum. Among as it is very rarely made use of: it appears from its sensible qualities to be a medicine of much the same kind with valerian, which is indisputably preferable to it. The root of the third species has been sometimes sent over from America instead of that of ipecacuanha, and mischievous effects have been produced by it. Those who cultivate this plant ought to be careful that none of its milky juice mix with any thing which is taken inwardly.

ASCODUTÆ, in antiquity, a fect of heretics, in the fecond century, who rejected all use of symbols and facraments, on this principle, That incorporcal things cannot be communicated by things corporeal, nor divine mysteries by any thing visible.

ASCOLI, formerly Afculum Apulum, a pretty large and populous town of Italy, in the marquifate of Ancona, and territory of the church; it is a bishop's see, and feated on a mountain, at the bottom of which runs the river Fronto. E. Long. 15. 20. N. Lat. 42. 47.

Ascoul de Satriano, formerly Asculum Picenum, an episcopal city of Italy, in the kingdom of Naples; seated on a mountain. E. Long. 15. 5. N. Lat. 42. 8.

ASCOLIA, in Grecian antiquity, a festival celebrated by the Athenian husbandinen in honour of Bacchus, to whom they facrifice a he goat, because it destroys the vines (Ovid. Fast. i. 357); and, to show the greater indignity to an animal hated by Bacchus; the peafants, after having killed him, made a foot-ball of his skin. Virgil has beautifully described the occasion of the facrifice and manner of celebrating the feftival, Georg. ii. 380.

ASCRIPTITII, or Apscriptitii, were a kind of villains, who, coming from abroad, fettle in the lands of some new lord, whose subjects or servants they commence; being so annexed to the lands, that they may be transferred and fold with the same. Ascriptitii is fometimes also used in speaking of aliens or foreigners newly admitted to the freedom of a city or country.

ABCRIPTITII was also used in the military laws for Ascripting the recruits appointed to supply the losses of the legions, called also Accenfi.

Αĥ.

ASCRIVIUM (anc. geog.), a town of Dalmatia, on the Sinus Rhizicus (Pliny, Ptolemy): Now Catturo (Harduin); the capital of the territory of Cattaro, in Venetian Dalmatia. E. Long. 19. 20. Lat. 45.25.

ASCULUM APULUM (anc. geog.), a town of Apulia, much mentioned in the war with Pyrrhus (Florus, Plutarch): Now called Ascoli; a city of the Capitanata, in the kingdom of Naples. E. Long. 16. 30. Lat. 41. 15.

Asculum Picenum (anc. geog.), a town of the Piceni (Czefai); and the capital (Florus): Now Afcoli, in the marquifate of Ancona, on the river Fronto. E. Long. 15. 5. Lat. 42. 50.

ASCYRUM, PFTIR'S WORT: A genus of the polyandria order, belonging to the polydelphia class of plants; and in the natural method ranking under the 20th order, Rotacea. The caly x confifts of four leaves; the corolla has four petals; the filaments are numerous, and divided into four bundles. There are three species, the crux andrew, the hypericoides and the villofum, all natives of the West Indies or America, but possessing no property worthy of notice.

ASDRUBAL, the name of feveral Carthaginian generals. See CARTHAGE.

ASEKI, or Astrai, the name which the Turks give to the favourite fultanesses who have brought forth fons. These are greatly diffinguished above others in their apartments, attendants, penfions, and honours. They have sometimes shared the government. The fultana who full prefents the emperor with a male child, is reckoned the chief favourite, is called Luyuk afeki, and ranks as a legitimate wife: though, from the time of Bajazet I, the fultans are forbid to marry by a public law, which Solyman II. violated in favour of Rox-

ASELLUS, in zoology, the trivial name of a species of omfens. See Ontseus.

ASGILI. (John), a late humorous writer, was bred to the law, and practifed in Ireland with great fuccess. He was there elected a member of the house of commons, but was expelled for writing a treatife on the possibility of avoiding death; and being afterwards chosen a member for the borough of Bromber in Suffex, he was also on the same account expelled the parliament of England. After this, he continued 30 years a prisoner in the Mint, Fleet, and King's-bench; during which time he published a multitude of finall political pamphlets, feveral of which were in defence of the succession of the house of Hanover, and against the pretender. He died in the rules of the King's-bench, in the year 1738, when he was upwards of fourfcore.

ASH, in botany. See Fraxinus.

As H-Hole, among chemists, is the lowest part of a furnance; and is intended to receive the after falling from the fire, and to give a passage to the air which is to be introduced into the furnace, to keep up the com-

As H-Wednesday, the first day of Lent; supposed to have been fo called from a cultom in the church, of sprinkling ashes that day on the heads of penitents then admitted to penance. See LENT.

Afhmole.

Albhorn Albhord. ASHBORN, a town in Derbyshire, scated between the rivers Dove and Compton, over which there is a stone bridge, in a rich soil. It is a pretty large town, though not so flourishing as formerly. W. Long. 1. 35. N. Lat. 53. 0.

ASHBURTON, a town in Devonshire. It sends two members to parliament, and is one of the four stannery towns. It is seated among the hills, which are remarkable for tin and copper; and has a very hand-some church; as also a chapel, which is turned into a school. It gives title of Baron to Dunning the late solicitor-general whose son now enjoys it. W. Long. 3. 10. N. Lat. 50. 30.

ASHBY BE LA ZOUCH, a market-town in Leicestershire, situated in W. Long. 1. 20. N. Lat. 52. 40. It had a castle which was long in the possession of the family of de la Zouch. It afterwards sell into the hands of Edward IV. who granted it to Sir Edward Hastings, created Baron Hastings, with license to make a castle of the manor-house, to which he adjoined a very high tower. It was demolished in 1648; but a great part of the tower is still standing. It now belongs to the earl of Huntingdon.

ASHDOD, or Azorus. See Azorus.

ASHES, the earthy particles of combustible subflances after they have been burnt.

If the ashes are produced from vegetable bodies, they contain a considerable quantity of fixed salt, blended with the terrene particles: and from these ashes the fixed alkaline salts called pot-ash, pearl-ash, &c. are extracted. See Potash, &c.

The ashes of all vegetables are vitrisiable, and found to contain iron.—They are also an excellent manure for cold and wet grounds. See Agricultures, No 20.

Several religious ceremonies depend upon the use of ashes. St Jerome relates, that the Jews in his time rolled themselves in ashes, as a sign of mourning. repent in fackcloth and ashes, is a frequent expression in Scripture for mourning and being afflicted for our There was a fort of lie and lustral water made with the ashes of a heifer sacrificed upon the great day of expiation; the after whereof were distributed to the people, and this water was used in purifications, as often as any touched a dead body, or was prefent at funerals, (Numb. xix. 17.) Tamar after the injury received from her brother Amnon, covered her head with ashes, (2 Sam. xiii. 19.) The Plalmist in great forrow fays, that he had eaten ashes as if it were bread, (Pf. cii. 9.); which, however, is to be confidered as an hyperbole. He fat on ashes, he threw ashes on his head; his food, his bread, was spoiled with the ashes wherewith he was covered.

The ancient Persians had a fort of punishment for Tome great criminals, which consisted in executing them in ashes. The criminal was thrown headlong from a tower 50 cubits high, which was filled with ashes to a particular height, (2 Mac. xiii. 5, 6.) The motion which the criminal used to disengage himself from this place, plunged him still deeper into it, and this agitation was further increased by a wheel which stirred the ashes continually about him till at last he was stiffed.

after continually about him till at last he was strifted.

FIFORD, a market town of Kent, situated about
12 mars fouth-west of Canterbury, in E. Long. 45.

Lat. 51. 15.

ASHLAR, a term used among builders; by which they mean common or free stones, as they come out of the quarry, of different lengths and thicknesses.

ASHLERING, among builders, figuifies quartering, to lath to, in garrets, about two and a half, or three feet high, perpendicular to the floor, up to the under fide of the rafters.

ASHMOLE (Elias), a great antiquary and herald, founder of the Ashmolean musæum at Oxford, was born at Litchfield in Staffordshire, 1617. In the early part of his life, he practifed in the law; and in the civil war had a captain's commission under the king, and was also comptroller of the ordnance. He mairied the Lady Mainwaring in 1649, and fettled at London; where his house was frequented by all the learned and ingenious men of the time. Mr Ashmole was a diligent and curious collector of manuscripts. In the year 1650, he published a treatise written by Dr Arthur Dee, relating to the philosophers stone; together with another tract on the same subject, by an unknown author. About the same time, he was busied in preparing for the press a complete collection of the works of such English chemists as had till then remained in manuscript. This undertaking cost him great labour and expence; and at length the work appeared, towards the close of the year 1652. He propoled at first to have carried it on to several volumes; but he afterwards dropped this delign, and feemed to take a different turn in his studies. He now applied himself to the study of antiquity and records: he was at great pains to trace the Roman road, which in Antoninus's Itinerary is called Bennevanna, from Weedon to Litchfield, of which he gave Mr Dugdale an account in a letter. In 1658, he began to collect materials for his History of the Order of the Garter, which he lived to finish, and thereby did no less honour to the order than to himself. In September following, he made a journey to Oxford, where he fet about giving a full and particular description of the coins presented to the public library by Archbishop Laud.

Upon the restoration of King Charles II. Mr Ashmole was introduced to his majefty, who received him very graciously; and on the 18th of June 1660, bestowed on him the place of Windfor herald. A few days after, he appointed him to give a description of his medals, which were accordingly delivered into his possession, and King Henry VIII.'s closet was assigned for his use. On the 15th of February, Mr Ashmole was admitted a fellow of the Royal Society; and on the 9th of February following, the king appointed him fecretary of Surinam, in the West Indies. On the 19th of July 1669, the university of Oxford, in consideration of the many favours they had received from Mr Ashmole, created him doctor of physic by diploma, which was presented to him by Dr Yates, principal of Brazen Nose college. On the 8th of May 1672, he presented his "Institution, laws, and ceremonies of the most noble order of the Garter," to the king; who received it very graciously, and as a mark of his approbation, granted him a privy feal for 400l. out of the custom of paper. the 26th January 1679, a fire broke out in the Middle Temple, in the next chamber to Mr Ashmole's, by which he loft a noble library, with a collection of 9000 coins, ancient and modern, and a vast repository of feals, charters, and other antiquities and curiofities;

Plate LVII

Afia. but his manuscripts and his most valuable gold medals were luckily at his house at Lambeth. In 1684, the university of Oxford having finished a magnificent repository near the theatre, Mr Ashmole sent thither his curious collection of rarities; which benefaction was confiderably augmented by the addition of his manuscripts and library at his death, which happened at Lambeth, the 18th of May, in the 76th year of his age. He was interred in the church of Great-Lambeth, in Surry, on the 26th of May 1692, and a black marble stone laid over his grave, with a Latin inscription.

> Besides the works which we have mentioned, Mr Ashmole left several which were published since his death, and some which remain still in manuscript.

> ASIA, one of the three general parts of our continent, and one of the four of the whole earth. separated from Europe by the Mediterranean sea, the Archipelago, the Black sea, the Palus Mzotis, the Don, and the Dwina, which fall into the White fea; and from Africa, by the Arabic gulf or Red fea, and the ishmus of Suez. All the other parts are furrounded by the ocean. The late discoveries show that it does not join to America, though it extends very near it: (See America, Nº 105.) It is fituated between 44 and 196 degrees of east longitude, and 1 and 74 degrees of north latitude. From the Dardanelles to the most castern shore of Tartary, it is 4740 miles in length; and from the most southern point of Malacca to the most northern point of Nova Zembla, it is #380 miles in breath.

> This walk extent of territory was fuccessively governed in past times by the Affyrians, the Medes, the Perhanagend the Greeks; but the immense regions of India and China were little known to Alexander, or the conquerors of the ancient world. Upon the deeline of those empires, great part of Asia submitted to the Roman arms; and afterwards; in the middle ages, the successors of Mahomet, or, as they are usually callad, Stracens, founded in Afia, in Africa, and in Eusope, a more extensive empire than that of Cyrus, Alexander, or even the Roman when in its height of power. The Saracen greatness ended with the death of Tamerlane; and the Turks, conquerors on every fide, took possession of the middle regions of Asia, which they Itill enjoy. Belides the countries possessed by the Turks and Rullians, Afra contains at prefent three large empires, the Chinese, the Mogul, and the Persian; upon which the lesser kingdoms and sovereignties of Alia generally depend. The prevailing form of government in this division of the globe is absolute monarchy. If any of them can be said to enjoy fome share of liberty it is the wandering tribes, as the Tartars and Arabs. Many of the Affatic nations, when the Dutch first came among them, could not conceive how it was possible for any people to live under any other form of government than that of a despotte monarchy. Turkey, Arabia, Persia, part of Tartary, and part of India, profess Mahometanism. The Persian and Indian Mahometans are of the sect of Hali, and the others of that of Omar; but both own Mahomet for their lawgiver, and the Koran for their rule of faith and life. In the other parts of Tartary, India, China, Japan, and the Afiatic islands, they are generally heathens and idolaters. Jews are to be found Voz. II. Part I.

everywhere in Asia. Christianity, though planted here with wonderful rapidity by the apostles and primitive fathers, suffered an almost total eclipse by the conquests of the Saracens, and afterwards of the Turks. Incredible indeed have been the hazards, perils, and fufferings of popilh millionaries, to propagate their doctrines in the most distant regions, and among the groffest idolaters; but their labours have hitherto failed of success, owing in a great measure to their own avarice, and the avarice and profligacy of the Europeans, who refort thither in fearch of wealth and dominion.

Asia may be divided into the following parts: Turkey in Alia, Arabia, Persia, the Mogul's empire, with the two peninsulas of the Indies; Tibet, China, and Corea; Great and Little Bukharia, with Chorasan; Tartary, Siberia, and the islands. The principal languages spoken in Asia are, the modern Greek, the Turkish, the Russian, the Tartarian, the Persian, the Arabic, the Malayan, the Chinese, and the Japanese. The European languages are also spoken upon the coafts of India and China.

Asia is looked upon as that part of the world which. of all others, has been most peculiarly diffinguished by heaven. There it was the first man was created; there the patriarchs lived, the law was given to Moses, and the greatest and most celebrated monarchies were formed; from thence the first founders of cities and nations in other quarters of the world brought their colonies. Lastly, In Asia Jesus Christ appeared : there it was that he wrought the falvation of mankind, that he died and rose again; and from thence it is that the light of the gospel was diffused over all the world. Laws, arts, sciences, and religion, almost all had their

original in Afia.

As Asia exceeds the other two parts of our continent, Europe and Africa, so it is superior to them in the ferenity of its air, the fertility of its foil, the deliciousness of its fruits, the fragrancy and balsamic qualities of its plants, spices, and gums; the falubrity of its drugs; the quantity, variety, beauty, and value of its gems; the richness of its metals, and the fineness of its filks and cottons. A great change indeed hath happened in that part of it called Turkey, which hath loft much of its ancient splendour, and from the most populous and best cultivated spot in Asia, is become a wild and uncultivated desert. The other parts of Asia continue much in their former condition; the foil being as remarkable for its fertility, as most of the inhabitants for their indolence, effeminacy, and luxury. This effeminacy is chiefly owing to the warmth of the climate, though in some measure heightened by custom and education; and the symptoms of it are more or less visible as the several nations are seated nearer or farther from the north. Hence the Tartars who live near the same latitudes with us, are as brave, hardy, firong, and vigorous, as any European nation. What is wanting in the robust frame of their bodies among the Chinese, Mogul-Indians, and all the inhabitants of the more fouthern regions, is in a great measure made up to them by the vivacity of their minds, and ingenuity in various kinds of workmanship, which our most skilful mechanics have in vain endeawoured to imitate.

The chief rivers of Asia are, the Euphrates and Ti-

gris, in Turkey; the Indus and Ganges, in India; the Kiang and Hoang-ho, in China; the Sir Amu and Wolga, in Western Tartary; the Saghalia Ula or Amur, in Eastern Tartary; the Irtish, Oby, Jenisea, and Lena, in Siberia. The lakes are, that prodigious one called the Gajphan Sea; and near that another very large one, but lately known to us, called Aral, or the lake of eagles. The Baikal is in Siberia, the Kokonor near Tibet, and the Tong Ping in China. The chief mountains are, those of Taurus in Turkey and Persia; the Imaus, between India and Tibet; and the Altaic chain, in Tartary.

The Afiatic islands are very numerous, infomuch that some reckon 150,000; but of this there is no certainty. However, they may be divided into those of the cast, west, south, and south-cast. Those that lie on the east of Alia are, the islands of Jello or Yedso and Japan, with feveral finall ones on the coast of Corea, the And of Formofa, and the Philippines. Those on the west are, the island of Cyprus, in the Mediterraneon, Scanderoon, off Natolia, and the ifle of Rhodes off Phischio, on the same coast. Those on the fouth are, the illes of the Maldives, in the Indian fea! the ific of Ceylon, off Cape Comorin; with a great many fmall ones in the gulf of Bengal. Those on the fouthealt are, the iffes of Sunda, as Sumatra, the iffes of Java, Borneo, &c. the Moluccas, the illes of Kumbava, Timor, &c.

Asia Minor, or Leffer Afia; the same with Natolia. Sie Natolia.

ASIARCH.E, (termed by St Paul, Chief of Asia, Act xix. 31.) were the Pagan pontiffs of Alia, chosen to reperintend and have the care of the public games, which they did at their own expence: for which reafon they were always the richest and most considerable men of the towns.

ASIDF, in the drama, fomething faid by an actor, which fome, or even all the other actors present are supposed not to hear; a circumstance justly condemned as being unnatural and improbable.

ASIITO, a town of Italy, in Perugia, and in the Pope's territories. F. Long. 23. 40. N. Lat. 43. 0.

ASILUS, or Horner-ray, a genus of infects belonging to the order of infects dipters. It has two wings; and a horny, firait, two valved beak. There are 17 species of this infect. Many of them wound in a very painful manner, and are particularly troubleforme to critic in low meadows; others of them are quite harml-is. See Plate LIV.

ASINARA, an illand of Italy, on the western coast of Sardinia. E. Long. 8. 30. N. Lat. 41. 0.

ASINIUS (Pollio), a Roman coulul and orator, diflinguished himself under Augustus by his exploits and his literary works. He is frequently mentioned with praises by Horace and Virgil, and is said to have collected the first library at Rome. He died at Frescati, et 80 years of age.

ASIONGABER, Estongeber, of Eziongeber, fown of Arshia P. trees, on the bay of Elath, a part of the Arabian gulf; the dock or flation for the ships Solomon and schoshaphat; an aucient town, menand the by Moles. It was afterwards called Beioe (Josephun).

ASISIA, or Assisia, a town of Liburnia (Prole-Antonine), now in ruine, but exhibiting many monuments of antiquity. It is the Affelia or Afferia of Pliny. This author, after having specified the Liburnian cities that were obliged to attend the congress or diet of Scardona, adds to the catalogue the free Afferians, immunesque Afferiates; and this people who created their own magistrates, and were governed by their own municipal laws, were no doubt more rich and powerful than their neighbours.

The vestiges of the walls of Asseria that still remain, are a sufficient proof of this; for their circumference is clearly diffinguishable above ground, and measures 3600 Roman feet. The space enclosed by them forms an oblong polygon, and they are built with common Dalmatian marble but not taken from the hill on which they fland, for that furnishes only foft stone. The walls are invested, both inside and out, with this marble: some of the stones are ten feet long, and they are all of confiderable dimensions. The thickness of these fortifications is commonly about eight feet: but at the narrowest extremity, which falls towards the foot of the hill, they are eleven feet thick; and, in some parts, their height full above ground reaches to near 30 feet. An antiquary, or even a simple lover of the fine arts, or of erudition, the Abbé Fortis observes, cannot help wishing at Podgraje (the modern name of Afferia), that some powerful hand quiequid sub terra eft in apricum proferit: and fuch a wish becomes Aronger when he reflects, that fince the destruction of that city no fearch has ever been made under ground, with a view to discover any thing curious, and yet these walls without doubt enclose a valuable deposite of antiquities, thrown down in heaps, who knows by what cause; perhaps naturally, by an carthquake, or perhaps by a fudden inundation of barbarians, which is ftill worfe. The gate now demolshed, the confiderable height of the walls to be feen in feveral places from without, some pieces of thick walls that still appear levelled to the ground among the buffes, are circumstances which give ground to hope that many costly monuments might be recovered out of these ruins. The magnificence of the remaining wall, and the many pieces of well cut stone and sine marble scattered. over the contiguous fields, afford lufficient proof that both good tafte and grandeur once flourished in that country. In the midft of the rubbish which covers the remains of Asseria, the parish church of the little village stands insulated; it is built of broken pieces of ancient ruins, taken as they happened to be nearest, mixed with mutilated inscriptions, and fragments of moble cornices.

ASKELON. See ASCALOR.

ASKERON, a place five miles from Doncaster, noted for a medicinal spring. It is a strong sulphureous water, and is flightly impregnated with a purging falt. It is recommended internally and externally in ftramous and other ulcers, scabs, leprofy, and timilar complaints. It is good in chronic obstructions, and in cases of worms and foulness of the bowels.

ASISIO, or Astrio, a city of the Pope's territories in Italy, fituated about 16 miles east of Perugia. E. Long. 13. 35. N. Lat. 43.

ASKRIG, a town in the N. Riding of Yorkshire. W. Long. c. 5. N. Lat. 53. 50.

ASLANI, in commerce, a filver coin, worth from 155 to 120 afpeon See Asper.

ASMONEUS,

Afaw.

ASMONEUS, or Assanoneus, the father of Simon, and chief of the Asmoneans, a family that reign-

ed over the Jews during 126 years.

ASNA, or Esna, a town in Upper Egypt, feated upon the Nile, believed by some authors to be the ancient Syena, though others fay the ruins of it are still to be seen near Assuan. It is so near the cataracts of the Nile, that they may be heard from thence. It contains feveral monuments of antiquity; and among the rest an ancient Egyptian temple, pretty entire, all painted throughout, except in some places that are effaced by time. The columns are full of hieroglyphic figures. This fuperb structure is now made use of for a stable, wherein they put oxen, camels, and goats. A little way from thence are the ruins of an ancient nunnery, faid to built by St Helena, furrounded with tombs.—Afna is the principal town in these parts, and the inhabitants are rich in corn and cattle. They drive a confiderable trade into Lower Egypt and Nubia, by means of the Nile, and also by the caravans that pale over the desert. The inhabitants are all Arabs, except about 200 Copts, the ancient inhabitants, and a fort of Christians. They are under the government of the Turks, who have a cadi, and the Arabs have two scheriffs of their own nation. E. Long. 31. 40. N.Lat.

ASOLA, a town of the Bressan in Italy, belonging to the republic of Venice. E. Long. 14. 18. N. Lat.

15. 15.

ASOLO, a town of Italy, in the Trevisan, seated on a mountain 17 miles north-west of Trevisan, and 10 north-cast of Bassano. E. Long. 12. 2. N. Lat. 45.

49.

ASOPH, a town of Cuban Tartary, in Asia, seated on the river Don, near its mouth, a little to the east of the Palus Mæotis, or Sea of Asoph. It has been several times taken and retaken of late years; but in 1739, the contending powers agreed that the fortifications should be demolished, and the town remains under the dominion of Russia. E. Long. 41. 30. N. Lat. 47. 18.

ASOPUS, a river of Phrygia Major, which, together with the Lycus, washes Laodicea, (Pliny).—Another of Bœotia, which running from Mount Cithæron, and watering the territory of Thebes, separates it from the territory of Platæa, and falls with an east course into the Euripus, at Tanagra. On this river Adrassus king of Sicyon built a temple to Nemesis, thence called Adrassia, From this river Thebes came to be surnamed Asopides, (Strabo). It is now called Asopo. A third Asopus, a river of Peloponnesus, which runs by Sicyon, (Strabo); and with a north-west course falls into the Sinus Corinthiacus, to the west of Corinth.—A fourth, a small river of the Locri Epicnemidii, on the borders of Thessay, (Pliny); rising in Mount Oeta, and falling into the Sinus Maliacus.

Asserus, a town of Laconia, (Paulanias); on the Sinus Laconicus, with a port in a peninfula, between Box to the east, and the mouth of the Eurotas to the west. The oitadel only remains standing, now called

by the failors Caftel Rampano.

ASOR, or HAZOR (anc. geog.), a town of the tribe of Judah, to the fouth-west, on the borders of Ascalon, (Joshua); as also Hasor-Hadata, translated by the seventy Armen Kaun (id).—Another Asor, A-

forus, or Hazor, a town of Galilee; called the capital of all the kingdoms to the north of Palestine. It was taken by Joshua; the inhabitants were put to the sword, and their houses burnt. It was afterwards rebuilt (Judges, I Sam.); but remained still in the hands of the Canaanites, though in the lot of the tribe of Naphthali, (Joshua). It lay to the north of the Lacus Samachonites, called in Scripture the Waters of Merom, (Josephus).

ASOW, a celebrated and important fortress of Rusfia, once a place of confiderable trade, but now demolished. It was situated in the district of Bachmut, near the place where the Greeks many centuries ago built the city of Tanais, which was very famous for itstrade, and underwent many vicillitudes. The Genoefe, who fettled a trade with Russia soon after the discovery of Archangel by Captain Chanceltor, became malters of this place, and gave it the name of Tune, or Catana: but the Tartars, who were very powerful in the fe parts, feem to have been in possession of it long before; for, as Busching informs us, there are Asow coins yet extant, on which is the name of Taktanufs Kan. From the Genoese it fell into the hands of the Turks, loft its trade, and became an inconfiderable town. In 1657, it was taken by the Costacks, who defended it against the Turks in 1641, and next year fet fire to it, and blew it up. The Turks rebuilt it with strong fortifications. The Russians laid claim to it in 1672, and took it in 1696; but, by the treaty of Pruth in 1711, it was restored to the Turks. In 1736, the Russians became mafters of Alow; but by the treaty of Belgrade they were obliged to relinquish it, and entirely destroy the

ASP, in natural history, a small poisonous kind of ferpent, whose bite gives a speedy but easy death. It is faid to be thus denominated from the Greek arms, shield, in regard to the manner of its lying convolved in a circle, in the centre of which is the head, which it exerts, or raifes, like the umbo or umbilious of a buckler. This species of serpent is very frequently mentioned by authors; but so carelefely described, that it is not eafy to determine which, if any of the species know a at prefent, may properly be called by this name. It is faid to be common in Africa, and about the banks or the Nile; and Bellonius mentions a finall species of ferpent which he had met with in Italy, and which had a fort of callous excrefeence on the forehead, which he takes to have been the aspis of the ancients. It is with the asp that Cleopatra is said to have despatched herrelf, and prevented the deligns of Augustus, who intended to have carried her captive to adorn his triumphal entry into Rome. But the fact is contested: Brown places it among his vulgar errors. The indications of that queen's having used the ministry of the asp, were only two almost infensible pricks found in her arm; and Plutarch fays it is unknown what she died of. At the fame time, it must be observed that the slightness of the pricks found in her arm furnishes no presumption against the fact; for no more than the prick of a needle point dipt in the poison was necessary for the purpose. See the article SERPENT.

Lord Bacon makes the afp the least painful of all the instruments of death. He supposes it to have an affinity to opium, but to be less disagreeable in its opetation; and his opinion seems to correspond with the

3 D 2

accounts

Afparagus.

accounts of most writers, as well as with the effects deferibed to have been produced upon Cleopatra; for which see the article already referred to.

The ancients had a plaster called de Acridor, made of this terrible animal, of great efficacy as a discutient of struma and other indurations, and used likewise against pains of the gout. The stefs, and skin or exuvia, of the creature, had also their share in the ancient materia medica.

ASPA, a town of Parthia, (Ptolemy), now Ispahan, (Holstenius). In Ptolemy the latitude seems to agree, being 33°; but whether the longitude does, is a ques-

tion. E. Long. 51. Lat. 32. 30.

ASPALATHUS, AFRICAN BROOM: a genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, Papilionacee. The calyx confifts of 5 divisions: the pod is oval, and contains 2 seeds. Of this genus there are 19 species; all of which are natives of warm climates, and must be preserved in stoves by those who would cultivate them here. The rosewood, whence the oleum rhodii is obtained, is one of the species, but of which we have yet had no particular description. The wood is heavy, oleaginous, somewhat sharp and bitter to the taste, of a strong smell and purple colour. It is called referenced or lignum Rhodium, either on account of its sweet smell, or of its growth in the island of Rhodes. It was anciently in much repute as an altringent, strengthener, and drier : but it is now disused in internal practice. It affords an oil of an admirable scent, reputed one of the best of perfumes: it is chiefly used in scenting poinatums and liniments.

ASPARAGUS, SPARAGUS, SPERAGE, Or SPAR-ROW GRASS: A genus of the monogynia order, belonging to the hexandria class of plants; and in the natural method ranking under the 11th order, Sarmentaces. The calyx is quinquepartite, and erect; the 3 inferior petals are bent outwards; the berry has 3 cells, and contains 2 feeds.—The species are 10; but the only one cultivated in the gardens is that with an upright herbecous stalk, bushly leaves, and equal stipula; or the common asparagus. The other species are kept only in the gardens of the curious for the sake of warrety.

Culture. The garden asparagus is with great care cultivated for the use of the table. The propagation of this useful plant is from seed: and as much of the fuccess depends upon the goodness of the seed, it is much better to fave it than to buy it at the shops. The manner of faving it is this: Mark with a flick some of the fairest buds; and when they are run to berry, and the stalks begin to dry and wither, cut them up; rub off the berries into a tub, and pouring water upon them, rub them about with your hands: the hulks will break and let out the feed, and will fwim away with the water in pouring it off; so that in repeating this two or three times, the feeds will be clean washed, and found at the bottom of the tub. These must be spread on a mat to dry, and in the beginning of February must be fown on a bed of rich earth. They must not be fown too shick, and must be trad into the ground, and the earth sked over them smooth: the bed is to be kept clear weeds all the fummer; and in October, when the

stalks are withered and dry, a little rotten dung must Asparagua. be spread half an inch thick over the whole surface of the bed. The spring following, the plants will be fit to plant out for good; the ground must therefore be prepared for them by trenching it well, and burying a large quantity of rotten dung in the trenches, fo that it may lie at least fix inches below the surface of the ground: when this is done, level the whole plot exactly, taking out all the loofe flones. This is to be done just at the time when the asparagus is to be planted out; which must be in the beginning of March, if the foil is dry and the feafon forward; but in a wet foil, it is better to wait till the beginning of April, which is about the season that the plants are beginning to shoot. The season being now come, the roots must be carefully taken up with a narrow pronged dung fork, shaking them out of the earth, separating them from each other, and observing to lay all their heads even, for the more convenient planting them; which must be done in this manner: Lines must be drawn at a fcot diffance each, straight across the bed; these must be dug into small trenches of six inches deep, into which the roots must be laid, placing them against the fides of the trench with their buds in a right polition upwards, and so that, when the earth is raked over them, they may be two inches under the furface of the ground. Between every four rows a space of two feet and a half should be left for walking in, to cut the asparagus. When the asparagus is thus planted, a crop of onions may be fown on the ground, which will not at all hurt it. A month after this, the asparagus will come up, when the crop of onions must be thinned, and the weeds carefully cleared away. About August the onions will be fit to pull up. In October following, cut off the shoots of the alparagus within two inches of the ground, clear well all weeds aways. and throw up the earth upon the beds, so as to leave them five inches above the level of the alleys. A row of coleworts may be planted in the middle of the alleys, but nothing must be now sown on the beds. In the fpring the weeds must be hoed up, and all the summer the heds kept clear of weeds. In October they must be turned up, and earthed again, as the preceding feason. The second spring after planting, some of the young afparagus may be cut for the table. The larger shoots should only be taken, and these should be cut at two inches under ground, and the beds every year managed as in the second year. But as some people are very fond of early asparagus, the following directions are given by which it may be obtained any time in winter: Plant some good roots at one year old in a moist rich foil, about eight inches apart; the fecond and third years after planting, they will be ready to take up for the hot beds; these should be made pretty strong, about three feet thick, with new stable dung that hasfermented a week or more; the beds must be covered with earth fix inches thick; then against a ridge made at one end, begin to lay in your plants, without trimming or cutting the fibres, and between every row lay a little ridge of fine earth, and proceed thus till the bed is planted; then cover the bed two inches thick with earth, and encompals it with a straw band, and in a week, or as the bed is in the temper, put on the frames and glasses, and lay on three inches thick of freth

Aspalls, fresh earth over the beds, and give them air and add Aspasti- fresh heat to them as it requires. These beds may be made from November till March, which will last till

the natural grafs comes on.

Medicinal Uses. The roots have a bitterish mucilaginous taste, inclining to fweetness; the fruit has much the same kind of taste; the young shoots are more agreeable than either. Asparagus promotes appetite, but affords little nourishment. It gives a strong ill fmell to the urine in a little time after eating it, and for this reason is chiefly supposed to be diuretic: it is likewise esteemed aperient and deobstruent; the root is one of the five called opening roots. Some suppose the shoots to be most efficacious; others, the root; and others, the bark of the root. Stahl is of opinion that none of them have any great share of the virtues usually ascribed to them. Asparagus appears from experience to contribute very little either to the exciting of urine when suppressed, or increasing its discharge; and in cases where aperient medicines generally do service, this has little or no effect.

ASPASIA of MILETUS, a courtesan who settled at Athens under the administration of Pericles, and one of the most noted ladies of antiquity. She was of admirable beauty: yet her wit and eloquence, still more than her beauty, gained her extraordinary reputation among all ranks in the republic. In eloquence she furpassed all her contemporaries; and her conversation was fo entertaining and instructive, that not with standing the dishonourable commerce she carried on in semale virtue, persons of the first distinction, male and semale, reforted to her house as to an academy: she even numbered Socrates among her hearers and admirers. She captivated Pericles in fuch a manner, that he dismissed his own wife, in order to espouse her; and, by her universal knowledge, irresistible elecution, and intriguing genius, the in a great measure influenced the administration of Athens. She was accused of having excited, from motives of perfonal refentment, the war of Peloponnesus; yet, calamitous as that long and obstinate conside proved to Greece, and particularly to Athens, it may be suspected that Aspasia occasioned still more incurable evils to both. Her example, and still more her instructions, formed a school at Athens, by which her dangerous profession was reduced into system. The companions of Aspasia served as models for painting and flatuary, and themes for poetry and panegyric. Nor were they merely the objects, but the authors of many literary works, in which they established rules for the behaviour of their lovers, particularly at table; and explained the art of gaining the heart and captivating the affections. The drefs, . behaviour, and artifices of this class of women, became continually more seductive and dangerous; and Athens thenceforth remained the chief school of vice and pleafure, as well as of literature and philosophy.

ARPASIA, among ancient physicians, a constrictive medicine for the pudenda muliebria. It consisted only of wool, moistened with an infusion of unripe galls.

ASPASTICUM, (from worn Lopas, " I falute," in ecclefialtical writers), a place, or apartment, adjoining to the ancient churches, wherein the bishop and presbyters sat, to receive the falutations of the persons who came to visit them, defire their bleffing, or consult them on bufiness .- This is also called afpaticum dia-

conicum, receptorium, metatorium, or mesatorium, and sa- Aspect lutatorium : in English, "greeting-house."

ASPECT, in aftronomy, denotes the lituation of Alperugo.

the planets and stars with respect to each other.

There are five different aspects. 1. Sextile aspect is when the planets or stars are 60° distant and marked thus *. 2. The quartile, or quadrate, when they are 90° distant, marked . 3. Trine, when 120° distant, marked A. 4. Opposition, when 180° distant, marked o. And, 5. Conjunction, when both in the same degree, marked & .

Kepler, who added eight new ores, defines aspect to be the angle formed by the rays of two stars meeting on the earth, whereby their good or bad influence is measured: for it is to be observed, that these aspects being first introduced by astrologers, were distinguished into benign, malignant, and indifferent; the quartile and opposition being accounted malign; the trine and fextile, benign or friendly; and the conjunction,

indifferent.

ASPEN TREE, in botany. See Populus.

ASPER, in grammar, an accent peculiar to the Greek language, marked thus ('); and importing, that the letters over which it is placed ought to be strongly aspirated, or pronounced as if an b were joined with them.

Asper, or Afpre, in commerce, a Turkish coin, three of which make a MEDINE.

ASPERA ARTERIA, in anatomy, the same with the windpipe or trachea. See ANATOMY, No 116.

ASPERIFOLIATE, or Asperifolious, among botanists, fuch plants as are rough-leaved, having their leaves placed alternately on their stalks, and a monopetalous flower divided into five parts .- They conftitute an order of plants in the Fragmenta methodi naturalis of Linnæus, in which are these genera, viz. tournefortia, cerinthe, fymphytum, pulmonaria, anchusa, lithospermum, myosotis, heliotropium, cynoglossum, asperugo, lycopsis, echium, borrago: magis minufve oleracca, mucilaginofa, et glutinofa funt. Lin. In the present system, these are among the pentandria monogynia..

ASPERIFOLIÆ PLANTAE, rough-leaved plants; the name of a class in Hermannus, Boerhaave, and Ray's methods, confifting of plants which have four naked feeds, and whose leaves are rough to the touch.

In Tournefort's System, these plants constitute the third fection or order of the fecond class; and in Linnæus's Sexual method, they make a part of the pen-

tandria monogynia.

ASPERITY, the inequality of the furface of any body, which hinders the hand from paffing over it freely.-From the testimony of some blind persons, it has been supposed that every colour hath its particular degree of asperity: though this has been denied by others. See the article BLIND.

ASPEROSA, a town of Turkey in Europe; it is a bishop's see, situated on the coast of the Archipela-

E. Long. 25. 20. N. Lat. 40. 58.

ASPERUGO, SMALL WILD BUGLOSS, in botany:: A genus of the pentandria monogynia class; and in the natural method ranking under the 49th order, Afperifolia. The calyx of the fruit is compressed, with folds flatly parallel, and finuous. There are two fpecies, viz. the procumbens, or wild bugloss, a native of

Britain.;;

Afperula, Britain; and the Egyptiaca, a native of Egypt. Hor-Afphaltites fes, goats, sheep, and swine eat the first species; cows are not fond of it.

> ASPERULA, WOODROOF: A genus of the monogynia order, belonging to the bexandria class of plants; and in the natural method ranking under the 47th order, Stellate. The corolla is infundibuliform; and the capfule contains two globular feeds. There are two species, the cynanchica and the odorata. Both of them grow wild in Britain, fo are feldom admitted into gardens. The first is found on chalky hills. The latter is a low umbelliferous plant, growing wild in woods and copfes, and flowering in May. It has an exceeding pleafant fmell, which is improved by moderate exficcation; the tafte is subfaline, and somewhat auftere. It imparts its flavour to vinous liquors. Afperula is fupposed to attenuate viscid humours, and strengthen the tone of the bowels; it is recommended in obltructions of the liver and biliary ducts, and by some in epilepfies and palfies; modern practice has nevertheless rejected it. The smell of it is faid to drive away ticks and other infects. The roots of the first are used in Sweden to dye red.

> ASPHALTITES, so called from the great quantity of bitumen it produces; called also the Dead Sea; and from its fituation, the Eafl Sea; the Salt Sea, the Sea of Sodom, the Sea of the Defert, and the Sea of the Plain, in the facred writings: A lake of Judea.

Many things have been faid and written of this famed, or, if they were indeed true, rather infamous lake; fuch as that it arose from the submersion of the vale of Siddim, where once flood, as is commonly reported, the three cities which perished in the miraculous conflagration, with those of Sodom and Gomorrah, for their unnatural and deteftable wickedness; on which account this lake has been looked upon as a lasting monument of the just judgment of God, to deter mankind from such abominations. Hence it is added, that the waters of the lake are fo impregnated with falt, fulphur, and other bituminous stuff, that nothing will fink or live in it; and that it calls such stench and smoke, that the very birds die in attempting to fly over it. The defeription likewise of the apples that grew about it, fair without, and only ashes and bitterness within, were looked upon as a farther monument of God's anger. So likewife the description which many travellers give not only of the lake, but of all the country round about, of the whole appearing dreadful to behold, all fulphureous, bituminous, flinking, and fuffocating: and lastly, what hath been farther affirmed of the ruins of the five cities being still to be feen in clear weather, and having been actually feen in thefe latter times; all these surprising things, and ill-grounded notions, though commonly, and fo long, received among Christians, liave been of late fo much exploded, not only by the testimony of very credible witnesses, but even by arguments drawn from Scripture, that we must give them up as invention unless we will suppose the face and nature of all the othings to have been entirely change ed. Those, in particular, of bodies not finking in the water, and of birds being fifled by the exhalations of it, appear now falle in fact. It is true, the quantity of falt, alum and fulphur, with which it is impregnated, render it so much specifically heavier (Dr Pococke fays one-fifth) than fresh water, that bodies will not so

eafily fink : yet that author, and others, affure us, Afphaltices. they have fwam and dived in it; and, as to the birds, we are told likewife, that they will fly over it without any harm. To reconcile these things with the experiments which Pliny * tells us had been made . Not. Hift. by Vefpasian, is impossible, without supposing that Lib. V. cup. those ingredients have been since much exhausted, 15. which is not at all improbable; fuch quantities of them, that is, of the bitumen and falt, having been all along, and being still taken off, and such streams of fresh water continually pouring into it, as may reasonably be supposed to have considerably diminished its gravity and denfenefs. For, with respect to its salt, we are told, the Arabs make quantities of it from that lake, in large pits about the shore, which they fill with that water, and leave to be crystallized by the fun. This falt is in fome cases much commended by Galen, as very wholesome, and a strengthener of the stomach, &c. on account of its unpleasant bitterness.

What likewife relates to the constant smoke ascending from the lake, its changing the colour of its water three times a-day, so considently affirmed by Josephus + + B.d. Jul. and other ancients, and confirmed by Prince Radziville Lib. V. cap. and other moderns, who pretend to have been eye-5. witnesses of it, is all now in the same manner exploded by others of more modern date, and of at least equal candour. The unhealthiness of the air about the lake was affirmed by Josephus and Pliny, especially on the west: the monks that live in the neighbourhood confirm the same, and would have dissuaded Dr Pococke from going to it on that account; and, as he ventured to go and bathe in it, and was, two days after, feized with a dizziness, and violent pain in the stomach, which lasted near three weeks, they made no doubt but it was occasioned by it; and he doth not seem to contradict them. As to the water, it is, though clear, fo impregnated with falt, that those who dive into it come out covered with a kind of faline matter. There is one remarkable thing relating to this lake, generally agreed on by all travellers and geographers; viz. that it receives the waters of Jordan, a confiderable river, the brooks of Jabbok, Kishon, Arnon, and other fprings, which flow into it from the adjacent mountains, and yet never overflows, though there is no visible way to be found by which it discharges that great influx. Some naturalists have been greatly embarraffed to find a discharge for these waters; and have therefore been inclined to suspect the lake had a communication with the Mediterranean. But, besides that we know of no gulf to corroborate this supposition, it has been demonstrated by accurate calculations, that evaporation is more than sufficient to carry off the waters brought by the river. It is, in fact, very confiderable; and frequently becomes fensible to the eye, by the fogs with which the lake is covered at the rifing of the fun, and which are afterwards dispersed by the heat. It is enclosed on the east and west with exceeding high mountains, many of them craggy and dreadful to behold. On the north it has the plain of Jericho; or, if we take in both fides of the Jordan, it has the Great Plain, properly so called, on the fouth; which is open, and extends beyond the reach of the eye. Jofephus gives this lake 580 furlongs in length, from the mouth of the Jordan to the town of Segor, on the opposite end, that is about 22 leagues; and about 150

furlongs,

Afphaltites furlongs or 5 leagues, in its greatest breath; but our modern accounts commonly give it 24 leagues in length, and 6 or 7 in breadth. On the well fide of it is a kind of promontory, where they pretend to show the remains of Lot's metamorphofed wife. Josephus fays it was still standing in his time; but when Prince Radziville inquired after it, they told him there was no fuch falt pillar or flatue to be found in all that part. However, they have found means, about a century after him to recover, as they pretended to assure Mr Maundrel, a block or stump of it, which may in time grow up, with a little art, into its ancient bulk.

It is to be observed here, that the name of Dead Sea is not to be found in the facred writings; but hath been given to this lake because no creature will live in it, on account of its excessive saltness, or rather bituminous quality; for the Hebrews rank fulphur, nitre, and bitumen under the general name of falt. However, fome late travellers have found cause to suspect the common report of its breeding no living creature; one of them having observed, on the shore, two or three shells of fish like those of an oyster, and which he supposes to have been thrown up by the waves, at two miles distance from the mouth of the Jordan, which he there takes notice of, left they should be suspected to have been brought into the lake by that way. And Dr Pococke, though he neither faw fish nor shells, tells us, on the authority of a monk, that some fort of fish had been caught in it; and gives us his opinion, that as fo many forts live in falt water, fome kind may be fo formed as to live in a bituminous one. Mr Volney, however, affirms that it contains neither animal nor vegetable life. We fee no verdure on its banks, nor are fish to be found found within its waters. But he adds, that it is not true that its exhalations are pelliferous, fo as to destroy birds flying over it. " It is very common (fays he) to fee swallows skimming its surface, and dipping for the water necessary to build their nests. The real cause which deprives it of vegetables and animals is the extreme faliness of the water, which is infinitely stronger than that of the sea. The soil around it, equally impregnated with this falt, produces no plants; and the air itself, which becomes loaded with it from evaporation, and which receives also the sulphureous and bituminous vapours, cannot be favourable to vegetation: Hence the deadly aspect which reigns around this lake. In other respects, the ground about it, however, is not marshy; and its waters are limpid and incorruptible, as must be the case with a dissolution of falt. The origin of this mineral is easy to be discovered; for on the fouth-west shore are mines of fossil salt, of which I have brought away feveral specimens. They are fituated in the fide of the mountains which extend along that border; and, from time immemorial, have supplied the neighbouring Arabs, and even the city of Jerusalem. We find also on this shore fragments of sulphur and bitumen, which the Arabs convert into a trifling article of commerce; as also hot fountains, and deep crevices, which are discovered at a distance by little pyramids built on the brink of them. We likewife find a fort of Rone, which, on rubbing, enits a noxious fmell, burns like bitumen, receives a polish like white alabaster, and is used for the paving of courtyards. At intervals, we also meet with unshapen blocks, which prejudiced eyes mistake for mutilated

flatues, and which pass with ignorant and superstitious Asi haltites pilgrims for monuments of the adventure of Lot's Alphaltumwife; though it is no where faid the was metamorphofed into stone like Niobe, but into falt, which must have melted the enfuing winter."

It is on account of this bitumen that it hath had the name of Afphaltite Lake, it being reported to have thrown up great quantities of that drug, which was much in use among the Egyptians, and other nations, for embalming of dead bodies. Josephus affures un, that in his days it role in lumps as big as an ox without its head, and some even larger. But whatever it may have formerly done, we are affored by Mr Maundrell and others, that it is now to be found but in small quantities along the shore, though in much greater near the mountains on both fides the lake. But the contrary is fince affirmed by two or more late travellers; one * Pococle's of whom tells us, that it is observed to float on the sur- Travels, face of the water, and to come on the shore after windy P. 56. weather, where the Arabians gather it, and put it to all the uses that common pitch is used for, even in the composition of some medicines; and another tells us, he was there informed, that it was raifed at certain † Share's times from the bottom, in large hemispheres, which, p. 374 as foon as they touch the furface, and are acted upon by the external air, burft at once, with great notice and fmoke, like the pulvis fulminans of the chemists, difperfing themselves about in a thousand pieces. From both these judicious authors we may couclide the reason of Mr Maundrell's miliake, both as to the lake's throwing it up only on certain feafons (that reverend gentleman might chance to be there at the wrong time); and likewife as to his not observing it about the thores, feeing the Arabs are there ready to gather it as foon as thrown up; all of them describe it as resembling our black pitch, fo as not to be didinguished from it but by its fulphureous fmoke and flench when fet on fire; and it hath been commonly thought to be the fame with that which our druggifts fell under the name of bitamen Judnieum, or Jewish pitch, though we have reason to think that this last is factitious, and that there is now none of the right afphaltum brought from Judea.

It hath, moreover, been confounded with a fort of blackish combustible stone thrown on the shore, and called by fome Mofes's flone, which being held in the flame of a candle, will foon burn, and caft a fmoke and intolerable flench; but with this extracidinary property, that though it lofes much of its weight and colour, it becoming in a manner white, yet it diminishes withing of its bulk. But thele, Dr Pococke tells us, are found about two or three leagues from the He concludes, however, from it, that a //ratum of that stone under the lake is probably one part of the matter that feeds the fubterraneous fire, and causes the bitumen to boil up out of it.

ASPHALTUM, BITUMEN JUDAICUM, OF JEWS PITCH, is a light folid bitumen, of a dutky colour on the outfide, and a deep shining black within; of very little tafte; and having fearcely any fmell, unless heated, when it emits a strong pitchy one. It is found in a fost or liquid state on the surface of the Dead Sea, and by age grows dry and hard. The fame kind of bitumen is met with likewife in the earth, in other parts of the world, in China, America, and in some places of Europe, as the Carpathian hills, France, Neufchatel,

Alphaltum &c. There are several kinds of Jews pitch in the Afphode- shops: but none of them are the genuine fort, and have little other title to their name than their being artificially compounded by Jews; and as they are a medley of we know not what ingredients, their medicinal use begins to be deservedly laid aside, notwithstanding the discutient, resolvent, pectoral, and other virtues attributed to this bitumen by the ancients. The true afphaltum was formerly used in embalming the bodies of the dead. The thick and folid afphalta are at prefent employed in Egypt, Arabia, and Persia, as pitch for ships; as the fluid ones, for burning in lamps, and for varnishes. Some writers relate, that the wall of Babylon, and the temple of Jerusalem, were cemented with bitumen instead of mortar. This much is certain, that a true natural bitumen, that for inflance which is found in the diffrict of Neufchatel, proves an excellent cement for walls, pavements, and other purposes, uncommonly firm, very durable in the air, and not penetrable by water. The watch and clock makers use a composition of asphaltum, fine lamp black, and oil of spike or turpentine, for drawing the black figures on dial plates: this composition is prepared chiefly by certain persons at Augsburg and Nuremberg. See the preceding article.

ASPHODELUS asphodel, of king?s spear: A genus of the monogynia order, belonging to the hexandria class of plants. The calyx is divided into fix parts; and the nectarium confifts of fix valves, cover-

ing the nectarium.-The

Species are five. 1. The luteus, or common yellow alphodel, hath roots composed of many thick sleshy fibres, which are yellow, and joined into a head at the top; from whence arife ftrong round fingle stalks near three feet high, garnished on the upper part with yellow star-shaped slowers, which appear in June, and the feeds ripen in autumn. 2. The ramofus, or branching asphodel, hath roots composed of fleshy fibres, to each of which is fastened an oblong bulb as large as a small potato; the leaves are long and flexible, having sharp edges; between these come out the flower-stalks, which arise more than three feet high, sending forth many lateral branches. The upper parts of these are adorned with many white star-shaped flowers, which grow in long spikes flowering gradually upward. They come out in the beginning of June, and the feeds ripen in 3. The ramofus, or unbranched asphodel, hath roots like the fecond, but the leaves are longer and narrower; the stalks are single, never putting out any fide-branches. The flowers appear at the fame time with the former, are of a purer white, and grow in longer spikes. 4. The albus, with keel-shaped leaves, hath roots composed of smaller fibres than the two last, nor are the knobs at bottom half so large: the leaves are long, almost triangular, and bollow like the keel of a boat; the stalks seldom rife above two feet high, and divide into feveral fpreading, branche st these are terminated by loose spikes of white flowers, smaller than those of the former. 5. The stulosus, or annual branching spiderwort, bath roots composed of many yollow fleshy fibres; the leaves are foread out from the drawn of the root, close to the ground, in a large child, these are convex on their under side, but plains the flower stalks rise immediately from the thousand grow about two feet high, dividing into

three or four branches upwards, which are adorned with Afphurewhite starry flowers, with purple lines on the outside. lite, These slower in July and August, and their seeds ri-Aspicueta.

pen in October.

Culture. The way to increase these plants is by parting their roots in August, before they shoot up their fresh green leaves. They may also be raised from seeds fown in August; and the August following the plants produced from these may be transplanted into beds, and will produce flowers the second year. They must not be planted in small borders, among tender flowers; for they will draw away all the nourishment, and flarve every thing elfe.

The Lancashire asphodel is thought to be very noxious to sheep, whenever, through poverty of pasture, they are necessitated to eat it : although they are said to improve much in their flesh at first, they afterwards die with symptoms of a diseased liver. This is the plant of which such wonderful tales have been told by Pauli, Bartholine, and others, of its softening the benes of fuch animals as fwallow it; and which they thence called gramen offifragum. Horned cattle cat it without any ill effect.

ASPHURELATA, in natural history, are femimetallic folile, fufible by fire, and not malleable in their purelt flate, being in their native flate intimately mixed with sulphur and other adventitious matter, and reduced to what are called ores,

Of this feries of folils there are only five bodies, each of which makes a diffinct genus; viz. antimony,

bismuth, cobalt, zinc, and quickulver.

ASPICUETA (Martin de), commonly called the Doctor of Navarre, or Doctor Navarrus, was descended of a noble family, and born the 13th of December 1491, at Varainyn, a small city of Navarre, not far from Pampeluna. He entered very young into the monastery of regular canons at Roncevaux, where he took the habit, which he continued to wear after he left the convent. He studied classical learning, natural and moral philosophy, and divisity, at Alcala, in New Castile, adopting chiefly the lystem of Petrus Lombardus, commonly called the Mafter of the Sentences. He applied to the fludy of the law at Ferrara, and taught it with applause at Toulouse and Cahors. After being first professor of canon law at Salamanca for 14 years, he quitted that place to be professor of law at Coimbra, with a larger salary. The duties of this office he discharged for the space of 20 years, and then religned it to retire into his own country, where he took care of bis nieces, the daughters of his deceased brothers. Having made a journey to Rome to plead the cause of Bartholomeo de Caranza archbishop of Toledo, who had been accused of herely before the tribunal of the inquilition in Spain, and whole cause was by the Pope's order, to be tried in that city, Aspicueta's writings, which were well known, procured him a most honourable reception. Pope Pius V. made him allistant to Cardinal Francis Acist, his vice penitentiary; and Gregory XIII. never passed by his door without calling for him, and stopped sometimes a whole hour to talk with him in the street. His name became so famous, that even in his lifetime the highest encomium on a learned man was to call him a Navarrus. He was confulted as an oracle. By temperance he prolonged his life to a great length. His economy enabled him to give **fubstantial**

Affaron.

Aspirate substantial proofs of his charity. Being very old, he used to ride on a mule through the city, and relieved all the poor he met; to which his mule was so well accustomed, that it stopped of its own accord at the fight of every poor man till its mafter had relieved him. He refused feveral honourable posts in church and state, that he might have leifure to correct and improve the works he had already written, and compose others. He died at the age of 94, on the 21st of June 1586. wrote a vast number of treatises, all which are either on morality or canon law.

ASPIRATE, in grammar, denotes words marked

with the spiritus asper. See Asper.

ASPIRATION, among grammarians, is used to denote the pronouncing a syllable with some vehemence.

ASPLENIUM, CETERACH: A genus of the order of filices, belonging to the cryptogamia class of plants. The parts of fuctification are fituated in the small sparse line under the disk of the leaves. There are 24 species. Two of these are natives of Britain, and grow upon old walls or moist rocks; one is called feolopendrium, or bart's tongue; the other is properly ceterach, also called fpleenwort. It has an herbaceous, fomewhat mucilaginous, roughish taste: it is recommended as a pectoral, and for promoting urine in nephritic cases. The virtue which it has been most celebrated for, is that which it has the least title to, viz. diminishing the spleen.

ASS, in zoology, is ranked as a species of equus,

or horfe. See Equus.

Coronation of the Ass, in antiquity, was a part of the ceremony of the feath of Vesta, wherein the bakers put bread crowns on the heads of these quadrupeds; Vvid Faft. Ecce' coronatis panis dependet afellis *. Hence, in an Vi. 311. ancient calendar, the ides of June are thus denoted; Festum of Veste. Afinus coronatur !- This honour, it forms, was done the beaft, because, by its braying, it had faved Vesta from being ravished by the Lampfacan god. Hence the formula, Vefta delicium eft

> ASSAI, in mulic, fignifies quick; and, according to others, that the motion of the piece be kept in a middle degree of quickness or flowness. As, affai allegro, fui presto. See ALLEGRO and PRESTO.

> ASSANCALA, a strong town in Armenia, near the river Arras, in the road between Erzerum and Érivan, and noted for its hot baths. It stands on a high hill; the walls are built in a spiral line all round the rock, and firengthened with square towers. ditches are about two fathoms over, cut out of hard

> rock. E. Long. 41. 30. N. Lat. 30. 46. ASSANCHIF, a town of Asia, in Diarbekir, seated on the river Tigris. E. Long. 42. 30. N. Lat.

.37. 20. ASSANS. See Assens.

ASSARTUM, in antiquity, denotes a small copper coin, being a part or diminutive of the as. The word morners is used by Suidas indifferently with ocolor and requeres, to denote a small piece of money; in which he is followed by Cujacius, who defines acragios by Minimus aris nummus. We find mention of the affarion in the gospel of St Matthew, chap. x. ver. 29.

ASSARON, or OMER, a measure of capacity, in ule among the Hebrews, containing five pints. It was Vor, II. Part II.

the measure of manna which God appointed for every Affino,

ASSASIN, or Assassin, a person who kills another with the advantage either of an inequality in the weapons, or by means of the fituation of the place,

or by attacking him at unawares.

The word affaffin is faid by fome to have been brought from the Levant, where it took its rife from a certain prince of the family of the Arfacida; popularly called Affafins, living in a castle between Antioch and Damateus, and bringing up a number of young men, ready to pay a blind obedience to his commands; whom he employed in murdering the princes with whom he was at enmity. But according to M. Volney, the word Haffaffen (from the root hafs, " to kill, to affalfinate, to liften, to furprife,") in the vulgar Arabic fignifies "Robbers of the night," perfons who lie in ambufh to kill; and is very univerfally understood in this fense at Cairo and in Syria. Hence it was applied to the Batenians, who flew by furprife. See the next ar-

There was a certain law of nations, an opinion, received in all the republics of Greece and Italy, whereby he that affaffinated an usurper of the supreme power was declared a virtuous man. At Rome efpecially, after the expulsion of the kings, the law was formal and folemn, and inflances of it admitted. The commonwealth armed the hand of any citizen, and created him magistrate for that moment.

Assassing, a tribe or clan in Syria, called also I/machans and Batanifts or Batenians. These people probably owed their origin to the Karmatians, a famous heretical fect among the Mahometans, who fettled in Persia about the year 1090; whence, in process of time, they fent a colony into Syria, where they became possessed of a considerable tract of land among the mountains of Lebanon, extending itself from the

neighbourhood of Antioch to Damaseus.

The first chief and legislator of this remarkable tribe appears to have been Hassan Sabah, a subtle impostor, who by his artifices made fanatical and implicit flaves of his fubjects. Their teligion was compounded of that of the Magi, the Jews, the Christians, and the Mahometans; but the capital article of their creed was to believe that the Holy Ghost resided in their chief; that his orders proceeded from God himfelf, and were real declarations of his divine pleafure. To this monarch the orientals gave the name of Scheik; but he is better known in Europe by the name of the Old Man of the Mountain. His dignity, instead of being here--ditary, was confirmed by election; where ment, that is, a superior multiplicity and enormity of crimes, was the most effectual recummendation to a majority of suffrages.

This chief, from his exalted refidence on the fummit of Mount Lebanon, like a vindictive deity, with the Thunderbolt in his hand, fent inevitable death to all quarters of the world; fo that from one end of the earth to the other, caliphs, emperors, fultans, kings, princes, Christians, Mahometans, and Jews, every nation and people, execrated and dreaded his fanguinary power, from the strokes of which there was no security. At the least fuggestion or whisper that he had threatened the death of any potentate, all immediately doubled their guards, and took every other precaution in their

3 E

Affay.

Affaffins. power. It is known that Philip Augustus king of France, on a premature advice that the Scheik intended to have him affaffinated, inflituted a new body guard of men diffinguished for their activity and courage, called fergens d'armes, with brass clubs, hows and arrows: and he himfelf never appeared without a club, fortified either with iron or gold. Most fovereigns paid fecretly a pension to the Scheik, however scandalous and derogatory it might be to the luftre of majefty, for the fafety of their persons. The Knights Templars alone dared to defy his fecret machinations and open force. Indeed they were a permanent difperfed body, not to be cut off by maffacres or affaffinations.

This barbarous prince was furnished with resources unknown to all other monarchs, even to the most abfolute despetic tyrant. His subjects would prostrate themselves at the foot of his throne, requesting to die by his hand or order, as a favour by which they were fure of passing into paradise. On them if danger made any impression, it was an emulation to press forward; and if taken in any enterprise, they went to the place of execution with a magnanimity unknown to others. Henry count of Champagne, who married Isabella daughter of Amaury king of Jerusalem, passing over part of the territory of the Assassin his way to Syria, and talking highly of his power, their chief came to meet him, " Are your subjects (said the old man of the mountain) as ready in their submission as mine?" and without staying for an answer, made a fign with his hand, when ten young men in white, who were flanding on an adjacent tower, inflantly threw themselves down. On another occasion, Sultan Malek-Shah summoning the Sheik to submit himself to his government, and threatening him with the power of his arms, should he hefitate to comply: the latter, very composedly turning himself towards his guards, faid to one of them, "Draw your dagger, and plunge it into your brenft;" and to another, " Throw yourself headlong from yonder rock." His orders were no fooner uttered than they were joyfully obeyed: and all the answer he deigned to give the sultan's envoy was, 44 Away to thy mafter, and let him know I have many thousand subjects of the same disposition." Men so ready to defiroy themselves were equally alert and resolute in being the ministers of death to others. At the command of their fovereign, they made no difficulty of stabbing any prince, even on his throne; and being well verled in the different dialects, they conformed to the drefs and even the external religion of the country, that they might with less difficulty strike the fatal blow required by their chief. With the Saracens they were Mahometans; with the Franks, Chriftians: in one place they joined with the Mamaluks; in another, with the ecclefiafties or religious; and under this difguife feized the first opportunity of executing their fanguinary commission. Of this we meet with an instance in the history of Saladia, while he was belieging Manbedge, the celebrated Hieropolis of antiquity. Being one day, with a few attendants, and they at fome distance, reconnoiting the place for the better disposition of the attack, a man rushed on him with a dagger in his hand, and wounded him on the head; but the fultan, as he was endeavouring to repeat his thoke, wrested the dagger from him, and, after receiving several wounds, laid him dead at his feet. Be- Assassins fore the fultan had well recovered himfelf, a fecond encountered him to finish the treachery of the former; but he met with the same fate: he was succeeded with equal fury by a third, who also fell by the hand of that magnanimous prince whom he was fent to affaffinate. And it was observed, that these wretches dealt about their fruitless blows as they lay in the agonies of death. With such rapidity was this transacted, that it was over before Saladin's guards could come to his affiftance. He retired to his tent, and in great perturbation throwing himfelf on his fopha, ordered his fervants to take a strict view of his household, and to cashier all suipected persons; at the same time asking with great earneilness, " Of whom have I deserved such treacherous usage?" But it afterwards appeared, that their villains had been fent by the old man of the mountain; of whom the vizir Kamschlegin had purchased the muider of Saladin, to free himfelf from fo great a warrior, whom he could not meet in the field. To animate them in their frantic obedience, the Scheik, before their departure on such attempts, used to give them a small foretaile of some of the delights which he assured them would be their recompense in paradise. Delicious soporific drinks were given them; and while they lay affeep, they were carried into beautiful gardens, where every allurement invited their fenses to the most exquisite gratifications. From these seats of vo-luptuousness, inflamed with liquor and enthusiastic views of perpetual enjoyments, they fallied forth to perform affaffinations of the blackeft dye.

This people once had, or at least they feigned to have, an intention of embracing the Christian religion. They reigned a long time in Perlia and on Mount Lebanon. Hulaku, a khan of the Mogul Tartare, in the year 655 of the Hegira, or 1254 of the Christian era, entered their country and dispossessed them of several places; but it was not till the year 1272 that they were totally conquered. This achievement was owing to the conduct and intrepidity of the Egyptian forces fent against them by the fultan Bibaris. It has, however, been thought, that the Drufes, who still reside among the eminences of Mount Lebapon, and whose religion and customs are so little known, are a remnant of those barharians.

ASSAULT, in law, is an attempt to offer to beat another, without touching him: as if one lifts up lis wane or his fift in a threatening manner at another; or firikes at him, but miffes him: this is an affault, infultus, which Finch describes to be " an unlawful setting upon one's person." This also is an inchoate violence, amounting confiderably higher than bare threats; and therefore, though no actual fuffering is proved, yet the. party injured may have redreft by action of trespass vi et armis, wherein he shall recover damages as a conpensation for the injury,

Assault, in the military art, a furious effort made to carry a fortified post, camp, or fortress, wherein the affailants do not fereen themselves by any works: while the affault continues, the batteries ceafe, for fear of killing their own men. The enfans perdus march first to the assault. See ENFANS Perdus.

ASSAY, Essay, or Say, in metallurgy, the proof or trial of the goodness, purity, value, &c. of metals and metalline substances. See Essay.

Affaying, Affay.

In ancient flatutes this is called touch; and those who had the care of it, Keepers of the touch .- Under Henry VI. divers cities were appointed to have touch for wrought filver plate, 2 Hen. VI. c. 14 .-- By this, one might imagine they had no better method of affaying than the simple one by the touchstone; but the case is far otherwise. In the time of King Henry II. the bishop of Salisbury, then treasurer, considering that though the money paid into the king's exchequer for his crown rents did answer numero et pondere, it might nevertheless be mixed with copper or brais: wherefore a conflictation was made, called the trial by combustion; which differs little or nothing from the present method of affaying filver. See a description of it in the Black Book in the Exchequer, written by Gervafe of Tilbury, c. xxi. This trial is also there called effaium, and the officer who made it is named fulor. The method still in use of assaying gold and filver was first established by an act of the English parliament 1354.

Assaying, are docimastica, in its extent, comprehends particular manners of examining every ore, or mixed metal, according to its nature, with the best adapted fluxes; so as to discover, not only what metals, and what proportions of metal, are contained in ores; but likewise how much fulphur, vitriol, alum, arsenic, fmelt, &c. may be obtained from every one respectively. See BLOW-PIPE, METALLURGY, and MINE-

RALOGY.

Assaying is more particularly used by moneyers and goldsmiths, for the making a proof or trial by the cuppel, or telt, of the fineness or purity of the gold and filver to be used in the coining of money, and manufacture of plate, &c. or that have been already used therein.

There are two kinds of affaying; the one before metals are melted, in order to bring them to their proper fineness; the other after they are struck, to see that the species be standard. For the first assay, the assayers use to take 14 or 15 grains of gold, and half a drachm of filver, if it be for money; and 18 grains of the one, and a drachm of the other, if for other occafions. As to the second affay, it is made of one of the pieces of money already coined, which they cut in four parts. The quantity of gold for an affay among us is fix grains; in France nearly the same; and in Germany, about three times as much.

The proper spelling of that word, however, is Es-SAY; under which article, therefore, the reader will

find the Subject more particularly treated.

AssAT Balance, or Effay Balance, the flat pieces of glass often placed under the scales of an assay balance, feem, by their power of electricity, capable of attracting, and thereby making the lighter scale preponderate, where the whole matter weighed is fo very small. See Effay BAYANCE.

The electricity of a flat furface of about three inches square has been known to hold down one scale, when there were about 200 grains weight in the other. See

BALANCE.

Assar Master, or Essay Master, an officer under certain corporations, intrusted with the care of making true touch, or affay, of the gold and filver brought to him; and giving a just report of the goodness or badnels thereof. Such is the affay mafter of the mint in the Tower, called also affayer of the king.

The affay mafter of the goldsmiths company is a fort. Astelyin of affidant worden, called also a touch worden, appointed to survey, affay, and mark all the filver work, &c. Affimblies. committed to him. There are also assay masters appointed by statute at York, Exeter, Bristol, Chester, Norwich, Newcastle, and Birmingham, for assaying wrought plate. The affay master is to retain eight grains of every pound Troy of filver brought to him; four whereof are to be put in the pix, or hox of deal, to be re-affayed the next year, and the other four to be allowed him for his watte and fpillings.

Note, The number of pennyweights let down in the affay mafter's report, is to be accounted as per pound, or fo much in every pound of 12 ounces Troy. For every 20 pennyweight, or ounce Troy, the filver is found by the affay to be worse than standard, or sterling, fixpence is to be deducted; Lecause every ounce will cost so much to reduce it to standard goodness, or

to change it for sterling.

In gold, for every carat it is fet down to be worfe than standard, you must account that in the ounce Troy it is worfe by fo many times 3s. 8d.; and for every grain it is fet down worfe, you must account it worse by so many times 11d. in the ounce Troy; and for every half grain 54d.: for so much it will cost to

make it of standard goodness, &c.

ASSELYN (John), a famous Dutch painter, was born in Holland, and became the disciple of Itaiali Vandervelde the battle painter. He distinguished himfelf in history paintings, battles, landscapes, animals, and particularly horses. He travelled into France and Italy; and was so pleased with the manner of Bambochio, that he always followed it. He painted many pictures at Lyons, where he married the daughter of a merchant of Antwerp, and returned with her to Holland. Here he first discovered to his countrymen a fresh and clear manner of painting landscapes, like Claude Isorraine; upon which all the painters imitated his style, and reformed the dark brown they had hitherto followed. Affelyn's pictures were fo much admired at Amflerdam, that they fold there at a high piece. He died in that city in 1660. Twenty-four prices of landscapes and ruins, which he painted in Italy, have been engraved by Perelle.

ASSEMBLAGE, the uniting or joining of things together; or the things themselves so united or joined. It is also used, in a more general sense, for a collection of various things fo dispoled and diverlished, that

the whole produces some agreeable effect.

ASSEMBLY, the meeting of feveral persons, in

the fame place, upon the fame defign.

Assembly, in the beau monde, an appointed meet. ing of fashionable persons of both sexes, for the sake of play, dancing, gallantry, conversation, &c.

ASSEMBLY, in the military art, the fecond beating of a drum before a march; at which the foldiers firike

their tents, roll them up, and stand to arms.

Assemblies of the clergy are called convocations, finide, councils. The annual meeting of the church of Scotland is called a General Affembly: In this affembly his majesty is represented by his commissioner, who disfolves one meeting, and calls another, in the name of the King, while the Moderator does the fame in the name of the Lord J. fus Christ.

A "SEMBLIES of the Roman people were called comition

Under

Affecs Afeta.

Under the Gothic governments, the supreme legislative power was lodged in an affembly of the states of the kingdom, held annually for the like purpofes as our parliament. Some feeble remains of this usage still Substit in the annual affemblies of the states of Languedue, Bretagne, and a few other provinces of France; but these are no more than shadows of the ancient asfemblies. It is only in Great Britain, Sweden, and Poland, that such assemblies retain their ancient powers and privileges.

ASSENS, a sea-port town of Denmark, situated upon the Little Belt, a strait of the Baltic, which feparates the iffe of Funen from the continent. It is the common passage from the duchy of Sleswick to

Copenhagen. E. Long. 10. 30. N. Lat. 55. 15.
ASSENT, in a general fense, implies an agreement

to fomething proposed or affirmed by another.

Royal Assent, the approbation given by the king to a bill in parliament, after which it becomes a law.

ASSER (John), or Asserius Manevensis, that is, Affer of St David's, bishop of Shirburn in the reign of Alfred the Great. He was born in Pembrokeshire in South Wales; and educated in the monaftery of St David's by the archbishop Asserius, who, according to Leland, was his kinfman. In this monaftery he became a monk, and by his affiduous application foon acquired universal same as a person of prosound learning and great abilities. Alfred, the munificent patron of genius, about the year 880, fent for him to court. The king was then at Dean in Wiltshire. He was so charmed with Affer, that he made him his preceptor and companion. As a reward for his fervices, he appointed him abbot of two or three different monasteries: and at last prompted him to the episcopal fee of Shirhurn, where he died and was buried in the year 910. I-Ir was, fays Pits, a man of a happy genius, wonderful modesty, extensive learning, and great integrity of life. He is faid to have been principally instrumental in perfunding the king to reftore the university of Oxford to its priftine dignity and luftre. He wrote, De vita et nebus gestis Alfredi, &c. Lond. 1574, published by Archbishop Parker, in the old Saxon character, at the end of Walfinghami Hift .- Francf. 1602, fol. Oxf. 1722, 8vo. Many other works are ascribed to this author by Gale, Bale, and Pits; but all doubtful.

ASSERIA. See Asisia.

ASSERTION, in the language of the schools, a. proposition advanced by the affertor, who avows the truth of it, and is ready to defend it.

ASSESSOR, an inferior officer of judice, appoint . I chiefly to affift the ordinary judge with his opinion and advice.

Assessor is also one who affelies, or fettles taxes

and other public dues.

ASSETS, in law, fignifies goods enough to discharge that burden which is call upon the executor or heir, is, fatisfying the debts and legacies of the tellator or anceltor. Affets are real or personal. Where a man both lands in fee fample, and dies frized thereof, the lands which come to his heir are affets real; and where he dies possussed of any personal estate, the jods which come to the executors are affets personal. The are also divided into affets per descent, and affets mainer. Affets by descent is where a person is in an obligation, and dies feized of lands which

descend to the heir, the land shall be affets, and the Asseveraheir shall be charged as far as the lands to him descended will extend. Affets inter maines is when a man in- Affiento. debted makes executors, and leaves them sufficient to pay his debts and legacies; or where fome commodity or profit arifeth to them in right of the tellator, which are called affets in their bands.

ASSEVERATION, a positive and vehement affir-

mation of fomething

ASSHETON (William), doctor of divinity, and rector of Beckenham, in Kent, was born in the year 1641, and was educated at Brazen-nofe College, Oxford. After entering into orders, he became chaplain to the duke of Ormond, and was admitted ductor of divinity in 1673. Soon after, he was nominated to a prebend in the church of York, presented to the living of St Antholin, London, and to the rectory of Beckenham in Kent. He was the first projector of the scheme for providing for clergymen's widows, and others, by a jointure payable out of the mercers company. He wrote feveral pieces against the Papists and Dissenters, and some devotional tracts. He died at Beckenham in September 1711, in the 70th year of

his age.

ASSIDEANS, or CHASIDEANS, (from the Hebrew chasidim, " merciful, pious"); those Jews who reforted to Mattathias to fight for the law of God and the liberties of their country. They were men of great valour and zeal, having voluntarily devoted thenselves toa more first observation of the law than other men. For after the return of the Jews from the Babylonish captivity, there were two forts of men in their church; those who contented themselves with that obedience only which was prescribed by the law of Moses, and who were called Zadikim, i. e. the righteous; and those who, over and above the law, superadded the constitutions and traditions of the elders, and other rigorous observances: these latter were called Chasidim, i. c. the pinus. From the former forming the Samaritans, Sadducees, and Caraites; from the latter, the Pharifees and the Effence.

ASSIDENT signs, in medicine, are symptoms which ulually attend a dileafe, but not always; hence differing from pathognomic figns, which are inseparable from the discale: e.gr. in the pleurily, a pungent pain in the fide; in an acute fever, difficulty of breathing, &c. collectively taken, are pathognomic figns; but that the pain extends to the hypochondrium or clavicle, or that the patient lies with more case on one side than on the other, are affident figus.

ASSIDUUS, or Apsiduus, among the Romans, denoted a rich or wealthy person. The word in this, sense is derived from as offic, q. d. a monied man. Hence we meet with affiduous sureties, affidui fidejuffon res, answering to what the French now call city fureties or securities, couligns burgeoir.

When Servius Tullius divided the Roman people into five classes, according as they were affected or taxed to the public, the richer fort who contributed affea were denominated official; and as their were the chief people of business who attended all the public concerns, those who were diligent in attendances, came to be denominated affidui.

ASSIENTO, a Spanish word fignifying a farm, in commerce, is used for a bargain between the king of

Spain and other powers, for importing negroes into the Spanish dominions in America, and particularly to Buenos Ayres. The first afficient was made with the French Guinea Company; and, by the treaty of Utrecht, transferred to the English, who were to furnish 4800 negroes annually.

ASSIGN, in common law, a person to whom a

thing is aflighed or made over.

ASSIGNATION, an appointment to meet. The word is generally understood of love meetings.

ASSIONEE, in law, a person appointed by another to do an act, transact some business, or enjoy a particular commodity.

ASSIGNING, in a general fense, implies the making over the right of one person to another. In a particular sense, it signifies the pointing out of something; as, an error, salse judgment, &c.

ASSIGNMENT, the transferring the interest one has in a lease, or other thing, to another person.

ASSIMILATION, in physics, is that motion by which bodies convert other bodies related to them, or at least such as are prepared to be converted, into their own substance and nature. Thus, slame multiplies itself upon oily bodies, and generates new slame; air upon water, and produces new air; and all the parts, as well smilar as organical, in vegetables and animals, first attract with some election or choice, nearly the same common or not very different juices for aliment, and afterwards assimilate or convert them to their own nature.

ASSISE, in old English law books, is defined to be an affembly of knights, and other substantial men, together with a justice, in a certain place, and at a certain time: but the word, in its present acceptation, implies a court, place, or time, when and where the writs and processes, whether civil or criminal, are de-

cided by judge and jury.

All the counties of England are divided into fix circuits; and two judges are affigned by the king's commission, who hold their assises twice a-year in every county (except London and Middlefex, where courts of nisi prim are holden in and after every term, before the chief or other judge of the several superior courts; and except the four northern counties, where the affifes are taken only once a-year) to try by a jury of the respective counties the truth of such matters of feet as are then under dispute in the courts of Weltmintter Hall. These judges of affile came into use in the room of the ancient justices in eyre, justiciarii in itinere; who were regularly established, if not first appointed, by the parliament of Northampton, A. D. 1176, 22 Hen. II. with a delegated power from the king's great court or aula regin, being looked upon as members thereof: and they afterwards made their circuit round the kingdom once in seven years for the purpole of trying causes. They were afterwards directed by magna charters. 12. to be fent into every county once a year to take or try certain actions then called recognitions, or affifes; the most difficult of which they are directed to adjourn into the court of common pleas to be these determined. The itinerant justices were fometimes mere justices of allife, or of dower, or of gaol delivery, and the like; and they had fometimes a more general commission, to determine all manner of causes, justiciarii ad omnia placita: but the profess

juffices of affile and nift prins are more immediately. Affile. derived from the statute Westm. 2. 13 Edw. I. c. 30. explained by feveral other acts, particularly the flatute 14 Edw. III. c. 16. and must be two of the king's justices of the one bench or the other, or the chief baron of the exchequer, or the king's ferjeants fworm. They usually make their circuits in the respective vacations after Hilary and Trinity terms; affifes being allowed to be taken in the holy time of Lent by confent of the bishops at the king's request, as expected in statute Westm. 1. 3 Edw. I. c. 51. And it was also usual, during the times of Popery, for the prelates to grant annual licenses to the justices of affile to adminither oaths in holy times: for oaths being of a facred nature, the logic of those deluded ages concluded that they must be of ecclesiastical cognizance. The prudent jealouly of our ancestors ordained that no man of law should be judge of affise in his own county; and a fimilar prohibition is found in the civil law, which has carried this principle so far, that it is equivalent to the crime of facrilege, for a man to be governor of the province in which he was born, or has any civil connexion.

The judges upon their circuits now fit by virtue of five feveral authorities: 1. The commission of the peace, in every county of the circuits: and all juffices of the peace of the county are bound to be prefent at the affiles; and sheriffs are also to give their attendance on the judges, or they shall be fined. 2. A commission of over and terminer, directed to them and many other gentlemen of the county, by which they are empowered to try treasons, selonies, &c. and this is the largest commission they have. 3. A commission of general gaol delivery, directed to the judges and the clerk of affife affociate, which gives them power to try every prisoner in the gaol committed for any offence whatfoever, but none but prisoners in the gaol; so that one way or other they rid the gaol of all the prifoners in it 4. A commission of affije, directed to the judges and clerk of affife, to take affifes; that is, to take the verdict of a peculiar species of jury called an affife, and fummoned for the trial of landed disputes. The other authority is, 5. That of nife print, which is a confequence of the commission of affife, being annexed to the office of those justices by the statute of Westm. 2. 13 Edw. I. c. 30. And it empowers them to try all questions of fact issuing out of the courts of Westminfter, that are then ripe for trial by jury. The original of the name is this: all causes commenced in the courts of Westminster Hall are by the course of the courts appointed to be there tried, on a day fixed in some Easter or Michaelmas term, by a jury returned from the county wherein the cause of action arises; but with this provilo, nifi prius justiciorii ad affisas capiendas venerant; unless before the day prefixed the judges of affile come into the county in quellion. This they are fure to do in the vacations preceding each Eafler and Michaelmas term, and there dispose of the cause; which faves much expence and trouble, both to the parties, the jury, and the witnesses.

The word affife (from the French offis, scated, settled, or established, and formed of the Latin verb affideo, "I" sit by,") is used in several different senses. It is sometimes taken for the sittings of a court; sometimes for its regulations or ordinances, especially those that fix

the standard of weights and measures: and sometimes it fignifies a jury, either because juries confisted of a fixed determinate number, or because they continued fitting till they pronounced their verdict. In Scots law, an effile or jury confilts of 15 fworn men (juratores), picked out by the court from a greater number, not exceeding 45, who have been summoned for that purpose by the sherist, and given in list to the defender, at ferving him with a copy of his libel.

ASSISIO, an episcopal town of Italy, in the duchy of Spoleto, built on the fide of a very high mountain. The cathedral of St Francis is very magnificent, and composed of three churches, one above another. E.

Long. 13. 35. N. Lat. 43. 4.

ASSITHMENT, a wiregeld, or compensation, by a pecuniary mulct; from the preposition ad, and the Sax. fithe, vice; quod vice supplicii ad expiandum deliaum

ASSOCIATION, the act of affociating, or conftituting a fociety, or partnership, in order to earry on fome scheme or affair with more advantage. - The word is Latin, offociatio; and compounded of ad, to, and Jocio, to join.

Association of Ideas, is where two or more ideas conflantly and immediately follow or succeed one another in the mind, so that one shall almost infalliably produce the other, whether there be any natural relation

between them or not. See METAPHYSICS.

Where there is a real affinity or connexion in ideas, it is the excellency of the mind, to be able to collect, compare, and range them in order, in its inquiries: but where there is none, nor any cause to be assigned for their accompanying each other, but what is owing to mere accident or habit; this unnatural affociation becomes a great imperfection, and is, generally speaking, a main cause of error, or wrong deductions in rea-Thus the idea of goblins and fprights, it has been observed, has really no more affinity with darkness than with light; and yet let a foolish maid inculcate these ideas often on the mind of a child, and raife them there together, it is possible he shall never be able to separate them again so long as he lives, but darknels shall ever bring with it those frightful ideas. With regard to this inflance, bowever, it must at the same time be observed, that the connexion alluded to appears far from being either unnatural or abfurd. See the article APPARITION.

Such wrong combinations of ideas, Mr Locke shows are a great cause of the irreconcilable opposition between the different fects of philosophy and religion: for we cannot imagine, that all who hold tenets different from, and fometimes even contradictory to, one another, should wilfully and knowingly impose upon themselves, and refuse truth offered by plain reason: but some loose and independent ideas are, by education, custom, and the constant din of their party, so coupled in their minds, that they always appear there together: these they can no more separate in their thoughts, than if they were but one idea, and they operate as if they were fo. This gives feule to jargon, demonstration to abfurdities, confishency to nonlense, and is the foundation of the greatest, and almost of all, the errors in the world.

Association forms a principal part of Dr Hartley's mechanical theory of the mind. He diffinguishes it into fynchronous and successive; and ascribes our simple and complex ideas to the influence of this principle Affociation or habit. Particular fensations result from previous prioritions conveyed through the nerves to the medul-Assumptit. lary substance of the brain; and these are so intimately affociated together, that any one of them, when impressed alone, shall be able to excite in the mind the ideas of all the reft. Thus we derive the ideas of natural bodies from the affociation of the feveral fensible qualities with the names that express them, and with each other. The fight of part of a large building fuggefts the idea of the rest instantaneously, by a synchronous affociation of the parts; and the found of the words, which begin a familiar sentence, brings to remembrance the remaining parts, in order, by fuccessive association. Dr Hartley maintains, that simple ideas run into complex ones by affociation; and apprehends, that by purfuing and perfecting this doctrine, we may fome time or other be enabled to analyze those complex ideas, that are commonly called the ideas of reflection, or intellectual ideas, into their feveral component parts, i. e. into the simple ideas of sensation of which they consist; and that this doctrine may be of confiderable use in the art of logic, and in explaining the various phenomena of the human mind.

Association of Parliament. In the reign of King William III. the parliament entered into a folemn affociation to defend his Majesty's person and government against all plots and conspiracies; and all persons bearing offices civil or military, were enjoined to subscribe the affociation to fland by King William, on pain of forfeitures and penalties, &c. by flat. 7 and 8. W. III.

ASSOILZIE, in law, to absolve or free.

ASSONANCE, in rhetoric and poetry, a term used where the words of a phrase or a verse have the same sound or termination, and yet make no proper rhyme. These are usually accounted vicious in English; though the Romans sometimes used them with elegancy : as, Militem comparavit, exercitum ordinavit, aciem luftravit.

ASSONANT RHYMES, is a term particularly applied to a kind of verfes common among the Spaniards, where a refemblance of found ferves instead of a natural rhyme. Thus, ligera, cubierta, terra, mefa, may answer each other in a kind of affonant rhyme, having each an e in the penult fyllable, and a in the last.

ASSUAN. See Syene.

ASSUMPSIT, in the law of England, a voluntary or verbal promise, whereby a person assumes, or takes upon him to perform or pay any thing to another.

A promise is in the nature of a verbal covenant, and wants nothing but the folemnity of writing and fealing to make it absolutely the same. If therefore it be to do any explicit act, it is an express contract, as much as any covenant; and the breach of it is an equal injury. The remedy indeed is not exactly the fame; fince, inflead of an action of covenant, there only lies an action upon the cafe, for what interior an affumpfit or undertaking of the defendant; the failure of performing which is the wrong or injury done to the plaintiff, the damages whereof a jury are to estimate As, if a builder promifes, undertakes, or assumes to Caius, that he will build and cover his house within a time limited, and fails to do it; Caius has an action, on the case against the builder for this

Aplit breach of his express promise, undertaking, or assumpfit; and shall recover a pecuniary satisfaction for the injury fustained by fuch delay. So also in the case of a debt by fimple contract, if the debtor promifes to pay it and does not, this breach of promife entitles the creditor to his action on the case, instead of being driven to an action of debt. Thus likewise a promisfory note, or note of hand not under feal, to pay money at a day certain, is an express assumplit; and the payee at common law, or by cultom and act of parliament the indorfee, may recover the value of the note in damages, if it remains unpaid. Some agreements indeed, though never to expressly made, are deemed of fo important a nature, that they ought not to rest in verbal promise only, which cannot be proved but by the memory (which sometimes will induce the perjury) of witnesses. To prevent which, the statute of frauds and perjuries, 29 Car. II. c. 3. enacts, that in the five following cases no verbal promise shall be sufficient to ground an action upon, but at the least some note or memorandum of it shall be made in writing, and figned by the party to be charged therewith: 1. Where an executor or administrator promises to answer damages out of his own estate. 2. Where a man undertakes to answer for the debt, default, or miscarriage, of another. 3. Where any agreement is made upon confideration of marriage. 4. Where any contract or fale is made of lands, tenements, or hereditaments, or any interest therein. 5. And lastly, Where there is any agreement that is not to be performed within a year from the marking hereof. In all these cases a mere verbal affumplit is void.

> From these express contracts the transition is easy to those that are only implied by law. Which are such as reason and justice dictate, and which therefore the law presumes that every man has contracted to perform; and, upon this prefumption, makes him answerable to fuch persons as suffer by his non-performance.

> Thus, r. If I employ a person to transact any businels for me, or perform any work, the law implies that I undertook, or assumed, to pay him so much as his labour deserved; and if I neglect to make him amends, he has a remedy for this injury by bringing his action on the case upon this implied assumpsit; wherein he is at liberty to fuggest that I promised to pay him so much as he reasonably deserved, and then to aver that his trouble was really worth fuch a particular fum, which the defendant has omitted to pay. But this valuation of his trouble is submitted to the determination of a jury; who will affels fuch a fum in damages as they think he really merited. This is called an affumpfit on a quan-

> 2. There is also an implied assumplit on a quantum valebat, which is very fimilar to the former; being only where one takes up goods or wares of a tradelman, without expressly agreeing for the price. There the law concludes, that both parties did intentionally agree that the real value of the goods should be paid; and an action on the case may be brought accordingly, if the vendee refuses to pay that value.

> 3. A third species of implied assumplit is when one has had and received money belonging to another without any valuable confideration given on the receiver's part; for the law construes this to be money had and received for the use of the owner only; and implies

that the person so receiving, promised and undertook Assumption to account for it to the true proprietor. And, if he unjuffly detains it, an action on the case lies against him for the breach of fuch implied promise and undertaking; and he will be made to repair the owner in damages, equivalent to what he has detained in fuch violation of his promife. This is a very extensive and beneficial remedy, applicable to almost every case where the defendant has received money which ex equo et bono he ought to refund. It lies for money paid by miltake, or on a confideration which happens to fail, or through imposition, extortion, or oppression, or where undue advantage is taken of the plaitiff's fituation.

4. Where a person has laid out and expended his own money for the use of another at his request, the law implies a promife of repayment, and an action will

lie on this affumplit.

5. Likewise, lifthly, upon a stated account between two merchants, or other perfons, the law implies that he against whom the balance appears has engaged to pay it to the other; though there be not any actual promife. And from this implication it is frequent for actions on the cafe to be brought, declaring that the plaintiff and defendant had fettled their accounts together, infinul computations (which gives name to this fpecies of allumpht); and that the defendant engaged to pay the plaintiff the balance, but has fince neglected to do it. But if no account has been made up, then the legal remedy is by bringing a writ of account, de computo; commanding the defendant to render a just account to the plaintiff, or show the court good emile to the contrary. In this action, if the plaintiff fucceeds, there are two judgments; the first is, that the defendant do account (qual computer) before auditors appointed by the court; and when fuch account is finished, then the second judgment is, that he do pay the plaintiff fo much as he is found in arrear.

6. The last class of contracts, implied by reason and construction of law, arises upon this supposition, that every one who undertakes any office, employment, truft, or duty, contracts with those who employ or mtrust him, to perform it with integrity, diligence, and skill: and if by his want of either of those qualities any injury accrues to individuals, they have therefore their remedy in damages, by a special action on the case. A few instances will fully illustrate this matter. If an officer of the public is guilty of neglect of duty, or a palpable breach of it, of non-feafance, or of mil-feafance; as, if the sheriff does not execute a writ sent to him, or if he wilfully makes a false return thereof; in both these cases, the party aggrieved shall have an action on the case for damages to be affested by a jury. If a theriff or gaoler fuffers a prisoner who is taken upca mesne process (that is, during the pendency of a funt) to escape, he is liable to an action on the cose. But it, after judgment, a gaoler or a sheriff permits a debtor to escape, who is charged in execution for a certain fum, the debt immediately becomes his own, and he is compellable by action of deld, being for a funi liquidated and afcertained, to fatisfy the creditor in his whole demand. An advocate or attorney that betray. the cause of their client, or, being retained, neglect to appear at the trial, by which the cause miscarries, are liable to an action on the case, for a reparation to their injured client. There is also in law always an implied:

Affumption implied contract with a common innkeeper, to fecure his gueft's goods in his inn; with a common carrier or barge mafter, to be answerable for the goods he carries; with a common farrier, that he shoes a horse well, without laming him; with a common taylor, or other workman, that he performs his bulinels in a workmanlike manner; in which, if they fail, an action on the case lies to recover damages for such breach of their general undertaking. Allo, if an innkeeper, or other victualler, bangs out a fign and opens his house for travellers, it is an implied engagement to entertain all persons who travel that way; and upon this universal affumpfit an action on the cafe will lie against him for damages, if he without good reason refuses to admit a traveller. In contracts likewise for sales, if the seller doth upon the fale warrant it to be good, the law annexes a tacit contract to this warranty, that if it be not fo, he shall make compensation to the buyer: else it is an injury to good faith, for which an action on the case will lie to recover damages.

> ASSUMPTION, a feltival in the Romish church, in honour of the miraculous afcent of the Virgin Mary into heaven: the Greek church, who also observe this fellival, celebrate it on the 15th of August with

great ceremony.

Assumption, in logic, is the minor or freed pro-

position in a categorical syllogism.

Assumption is also used for a consequence drawn from the propolitions whereof an argument is compofed.

Assumption, an island in North America, in the gulf of St Lawrence, at the mouth of the great river of the same name. It is covered with trees. W. Long.

60. 40. N. Lat. 49. 30.

Assumption, a large and handsome town of Proper Paraguay, on the river of the same name in South America. It is a bishop's see, is well peopled, and feated in a country fruitful in corn and fruits, whose trees are always green. There is likewife a quantity of pasture, and the air is temperate and falutary. W. Long. 60. 40. S. Lat. 34. 10.

ASSUMPTIVE ARMS, in heraldry, are fuch as a perfou has a right to assume, with the approbation of his fovereign, and of the heralds: thus, if a person, who has no right by blood, and has no coat of arms, fhall captivate in any lawful war any gentleman, nobleman, or prince, he is, in that case, entitled to bear the shield of that prisoner, and enjoy it to him and his heirs for ever.

ASSURANCE, or Insurance, in commerce. See Insurance.

ASSUROR, a merchant, or other person, who makes out a policy of affurance, and thereby infures a

fhip, house, or the like.

ASSUS, or Astos (and geog.), a town of Tross (though by others supposed to be of Mysia), and the same with Apollonia (Pliny); but different from the Apollonia on the river Rhyndacus. Ptolemy places it on the sea coast, but Strabo more inland; if he does not mean the head of an inland bay, as appears from Diodorus Siculus. It was the country of Cleanthes the Stoic philosopher, who succeeded Zeno. St Luke and others of St Paul's companions in his voyage (Acts xx. 13. 14.), went by sea from Troas to Assos; hat St Paul went by land thither, and meeting them at Assos, they all went together to Mytelene. It is still Assyria. called Affor. F. Long. 27. 30. N. Lat. 38. 30.

ASSYRIA, an ancient kingdom of Alia, concerning the extent, commencement, and duration of which, historians differ greatly in their accounts. Several ancient writers, in particular Ctefias and Diodorus Siculus, have affirmed, that the Affyrian monarchy, under Ninus and Semiramis, comprehended the greater part of the known world. Had this been the cafe, it is not likely that Homer and Herodotus would have omitted a fact to remarkable. The facred records intimate, that none of the ancient states or kingdoms were of confiderable extent; for neither Chedorlaomer, nor any of the neighbouring princes, were tributary or fubject to Affyria; and we find nothing of the greatness or power of this kingdom in the history of the judges and fucceeding kings of Ifrael, though the latter kingdom was oppressed and enslaved by many different powers in that period. It is highly probable, therefore, that Affyria was originally of small extent. According to Ptolemy, it was bounded on the north by Armenia Major; on the west by the Tigris; on the south by Sufiana; and on the east by Media.

It is probable, that the origin and revolutions of the Affyrian monarchy were as follow.—The founder of

it was Ashur, the second son of Shem, who went out

of Shinar, either by the appointment of Nimrod, or to elude the fury of a tyrant; conducted a large body of adventurers into Affyria, and laid the foundation of Nineveh (Gen. x. 11.) These events happened not long after Nimrod had established the Chaldwan monarchy, and fixed his refidence at Babylon. The Per-Playfair's fian historians suppose that the kings of Persia of the Chronelogy, first dynasty were the same with the kings of Assyria, of whom Zohah, or Nimrod, was the founder of Babel. (Herbelot Orient. Bibl. v. Bagdad). It does not, however, appear that Nimrod reigned in Affyria. The kingdoms of Babylon and Affyria were originally difunct and separate (Mionh v. 6.); and in this state they remained until Ninus conquered Babylon, and made it tributary to the Affyrian empire. Ninus the fuccessor of Ashur (Gen. z. 11. Died. Sic. lib. 1.), feized on Chaldan, after the death of Nimrod, and united the kingdoms of Affyris and Babylon. great prince is faid to have fubdued Alia, Perlia, Media, Egypt, &c. If he did fo, the effects of his conqueits were of no duration; for in the days of Abraham, we do not find that any of the neighbouring kingdoms were subject to Assyria. He was succeeded by Semiramis; a princess of an heroic mind; bold, enterpriling, fortunate; but of whom many fabulous things have been recorded. It appears, however, that there were two princesses of the same name, who flourished at very different periods. One of them was the confort of Ninus; and the other lived five generations before Nitocris queen of Nebuchadnezzar (Euseb. Chron. p. 58. Herod. lib. 1. c. 184.) This fact has not been attend-

ed to by many writers. Whether there was an uninterrupted feries of kings from Ninus to Sardanapalus, or not, is still a question. Some suspicion has arisen, that the list which Ctesias has given of the Affyrian kings is not genuine; for many names in it are of Persian, Egyptian, and Grecian extraction.

Nothing memorable has been recorded concerning the fucceffore

Aftell.

Assyria successors of Ninus and Semiramis. Of that effeminate race of princes it is barely faid, that they afcended the throne, lived in indolence, and died in their palace at Nineveh. Diodorus (L. ii.) relates, that, in the reign of Teutames, the Assyrians, solicited by Priam their valial, fent to the Trojans a supply of 20,000 foot and 200 chariots, under the command of Memnon, fon of Tithonus prefident of Persia: But the truth of this relation is rendered doubtful by the accounts of other writers.

Sardanapalus was the last of the ancient Assyrian kings. Contemning his indolent and voluptuous course of life, Arbaces governor of Media withdrew his allegiance, and rose up in rebellion against him. He was encouraged in this revolt by the advice and affiftance of Belefis, a Chaldean priest, who engaged the Babylonians to follow the example of the Medes. Thefe powerful provinces, aided by the Persians and other allies, who despifed the effeminacy, or dreaded the tyranny of their Affyrian lords, attacked the empire on all fides. Their most vigorous efforts were, in the beginning, unfoccefsful. Firm and determined, however, in their opposition, they at length prevailed, defeated the Assyrian army, belieged Sardanapalus in his capital, which they demolished, and became masters

of the empire, B. C. 821.

After the death of Sardanapalus, the Affyrian empire was divided into three kingdoms, viz. the Median, Affyrian, and Babylonian. Arbaces retained the supreme power and authority, and fixed his refidence at Echatana in Media. He nominated governors in Affyria and Babylon, who were honoured with the title of kings, while they remained subject and tributary to the Median monarchs. Belefis received the government of Babylon as the reward of his fervices; and Phul was intrusted with that of Assyria. The Assyrian governor gradually enlarged the houndaries of his kingdom, and was succeeded by Tiglath pileser, Salmanafar, and Sennacherib, who afferted and maintained their independency. After the death of Assar-haddon, the brother and successor of Sennacherib, the kingdom of Affyria was split, and annexed to the kingdoms of Media and Bahylon. Several tributary princes afterwards reigned in Nineveh; but no particular account of them is found in the annals of ancient nations. We hear no more of the kings of Affyria, but of those of Bahylon. Cyaxares king of Media, affifted Nebuchadnezzar king of Babylon, in the fiege of Nineveh. which they took and deftroyed, B. C. 606. The Chaldean or Babylonish kingdom was transferred to the Medes, after the reign of Nahonadius, fon of Evilmerodach, and grandfon of Nebuchadnezzar. He is ityled Belshazzar in the sacred records, and was conquered by Cyrus, B. C. 538.

ASSYTHMENT. See Assitument.

ASTA, an inland town of Liguria, a colony (Ptolemy) on the river Tanarus: Now Afti. E. Long.

8. 15. N. Lat. 44. 40.

Asra Regia, a town of Batica, (Pliny); fituated at the mouth of the Bietis which was choked up with mud, to the north of Cadiz: 16 miles distant from the port of Cadiz, (Antonine). Its ruins show its former greatness. Its name is Phoenician, denoting a frith or arm of the sea, on which it stood. It is faid to be the fame with XERA; which fee.

· Vol. II. Part II.

ASTABAT, a town of Armenia, in Asia, fituated Astabat near the river Aras, 12 miles fouth of Nakshivan. The land about it is excellent, and produces very good wine. There is a root peculiar to this country, called ronas; which runs in the ground like liquorice, and ferves for dveing red. It is very much used all over the Indies, and for it they have a great trade. E. Long. 46. 30. N. Lat. 39. 0.

ASTANDA, in antiquity, a royal courier or meffenger, the same with ANGARUS .- King Darius of Persia is said by Plutarch, in his book on the fortune of Alexander, to have formerly been an affanda.

ASTAROTH, or Ashtaroth, in antiquity, a goddels of the Sidonians .- The word is Syriac, and figuifies sheep, especially when their udders are turned with milk. From the fecundity of thefe animals, worth in Syria continue to breed a long time, they formed the notion of a deity, whom they called Allarorb, or Aftarte. See ASTARTF.

ASTAROTH, (and. geog.) the royal refidence of Og king of Bashan; whether the same with Astaroth Carnaim, is matter of doubt: if one and the same, it follows from Eufebiu 's account, that it lay in Biffian, and to the east of Jordan, because in the confines of Arabia.

ASTARTE, i.. Pagan mythology (the fingular of Aftaroth), a Phomeian goddels, called in Scripture the queen of beaven, and the goddefs of the Sidomons. -Solomon, in complement to one of his queens, erected an altar to her. In the reign of Ahab, Jezebel caufed her worthip to be performed with much pomp and ceremony: the had 400 priests; the wonlen were employed in weaving hangings or tabernacles for her; and Jeremiah observes, that "the children gathered the " wood, the fathers kindled the fire, and the women "kneaded the dough, to make cakes for the queen of

ASTARTE, (anc. geog.) a city on the other fide fordan; one of the names of Rabbath Ammon, in Arabia Petica, (Stephanus).

ASTEISM, in thetotic, a genteel frony, or handfome way of deciding another. Such e. gr. is that of ${f V}$ ırgil :

ui Bavium non odit, amet tua carmina, Mavi, &c.

Diomed places the characteristic of this figure, or species of irony, in that it is not grofs and ruffic, but in-

genious and polite.

ASTELL (Mary), the great ornament of her fex and country, was the daughter of - Aftell, an opulent merchant at Newcassle upon Tyne, where she was born about the year 1668. She was educated in a manner suitable to her station; and, among it other accomplishments, was mistress of the French, and had some knowledge of the Latin tongue. Her uncle, a clergyman, observing in her some marks of a promiting ger nius, took her under his toition, and taught her matthematics, logic, and philosophy. She left the place of her pativity when the was about 20 years of age, and fpent the remaining part of her life at London and at Chelfea. Here the purfued her fludies with great affiduity, made great proficiency in the above-mentioned sciences, and acquired a more complete knowledge of many classic authors. Among these Seneca, Epictetus, Hierocles, Antoninus, Tully, Plato, and Xeno. phon, were her principal favourites.

Aftell H Merebad

Her life was spent in writing for the advancement of learning, religion, and virtue; and in the practice of those religious duties which she so zealously and pathetically recommended to others, and in which perhaps no one was ever more fincere and devout. Her fentiments of piety, charity, humility, and other Chriflian graces, were uncommonly refined and fublime; and religion fat gracefully upon her, unattended with any forbidding airs of fourness or of gloom. Her mind was generally calm and ferene; and her conversation was innocently facetious, and highly entertaining. She would fay, "The good Christian only hath reason, and he always ought, to be cheerful;" and, "That dejected looks and melancholy airs were very unfeemly in a Christian." But these subjects she hath treated at large in some of her excellent writings.

She was remarkably abstemious; and seemed to enjoy an uninterrupted state of health till a few years before her death; when, having one of her breafts cut off, it so much impaired her constitution, that she did not long furvive it. This painful operation the underwent without discovering the least timidity, or so much as uttering a groan; and showed the same resolution and refignation during her whole illness. When she was confined to her bed by a gradual decay, and the time of her diffolution drew near, she ordered hershroud and coffin to be made and brought to her bedfide; and there to remain in her view, as a constant. memento of her approaching fate, and to keep her mind fixed on proper contemplation. She died in the year 1731, in the 63d year of her age, and was buried at Chelsea. She wrote, 1. A Serious Proposal to the Ladies. 2. An Essay in Defence of the Female Sex. 3. Letters concerning the Love of God. 4. Reflections upon Marriage. 5. Moderation truly stated. 6. The Christian Religion, as professed by a Daughter of the Church of England; and some other

ASTER, STARWORT: A genus of the polygamia fuperflua order, belonging to the fyngenefia class of plants; and in the natural method ranking under the 40th order, Composite discoides. The receptacle is naked; the pappus is simple; the rays of the corolla are 10; and the calyx is imbricated. There are above 30 species. All of them may be raifed from feed fown either in autumn or spring; but the greatest part of them being perennial plants, and increasing greatly at the roots, are generally propagated by parting their roots early in the spring, and they will grow in almost any foil or fituation; and the larger forts increase so fast, that, if not prevented, they will in a little time run over a large space of ground. They grow best in the shade: the lower kinds do not run fo much at the root. but should be taken up and transplanted every other year; which will make them produce much fairer flowers. Some few forts, which are natives of warm climates, will require artificial heat to raife them, if not to preferve them.

ASTER, or Stella Marina, in zoology., See Aste-

ASTERA. D, a province in the north-east part of Persia, his Tabristan on the east, part of the Caspian sea that of Jorjan on the north, Korasan on the west to somme on the fouth. It is a moun-

tainous country, except near the banks of the rivers Afterias, that almost surround it, where it is pleasant and fruitful, producing grapes of a prodigious size. In other parts the soil is sandy and barren. Asterabad is the chief town, which gives name to a gulf in the Persian sea, at the bottom of which it stands. E. Long. 54, 35. N. Lat. 36, 50.

ASTERIA, in zoology, a name by which fome authors have called the falco palumbarius, or gofbawk.

See FALCO.

ASTERIA is also the name of a gem, usually called the cat's eye or oculus cati. It is a very fingular and very beautiful ftone, and fomewhat approaches to the nature of the opal, in having a bright included colour, which feems to be lodged deep in the body of the flone, and shifts about, as it is moved, in various directions; but it differs from the opal in all other particulars, especially in its want of the great variety of colours seen in that gem, and in its superior hardness. It is usually found between the fize of a pea and the breadth of a fixpence; is almost always of a semicircular form, broad and flat at the bottom, and rounded and convex at the top; and is naturally smooth and polished. It has only two colours, a pale brown and a white; the brown feeming the ground, and the white playing about in it, as the fire colour in the opal. It is confiderably hard, and will take a fine polish, but is usually worn with its native shape and smoothness. It is found in the East and West Indies, and in Europe. The island of Borneo affords fome very fine ones, but they are usually small; they are very common in the lands of rivers in New Spain: and in Bohemia they are not unfrequently found immerfed in the same masses of jasper with the opal.

ASTERIA is also the name of an extraneous fossil, called in English the flar-flone. The folials are small, fhort, angular, or fulcated columns, between one and two. inches long, and feldom above a third of an inch in diameter: composed of several regular joints; when separated, each refembles a radiated flar. They are, not without reason, supposed to be a part of some featists. petrified, probably the asterias or lea dat. The asteria is also called astrices, aftroures, and asterifem. They may be reduced to two kinds; those whole whole bodies make the form of a star; and those which in the whole are irregular, but are adorned as it were with conficulations in the parts. Dr Lifter, for distinction's fake, only gives the name afteria to the former fort, diffinguishing the latter by the appellation of aftroiter; other naturalists generally use the two indiscriminately. The afteria spoken of by the ancients, appears. to be of this latter kind. The quality of moving in. vinegar, as if animated, is fcarce perceivable in the aftroites, but is fignal in the afteria. The former must be broken in small pieces before it will move; but the latter will move, not only in a whole joint, but in two or three knit together. The curious frequently meet with these stones in many parts of England: at Cleydon in Oxfordshire they are found rather larger than common, but of a fufter substance; for, on being left a fmall space of time in a strong acid, they may easily be separated at the joints in small plates.

ASTERIAS, STAR-FISH, or SEA-STAR, in zoology, a genus of infects of the order of vermes mollusca. It has a depressed body, covered with a coriaceous coat; is composed of five or more segments, running out from

Afterias a central part, and furnished with numerous tentacula: and has the mouth in the centre.- The conformation of the mouth is this: The under part of each lobe runs towards a point with the rest at the centre of the body; and these several productions of the rays make a fort of lips, the ends of each of which are armed with a number of fharp teeth, which ferve to take and convey the food into the body. From this mouth there goes a separate canal to all or many of the rays, which runs through their whole length, and becomes gradually narrower as it approaches the extremity. The tentacula refemble the horns of fnails, but ferve the animal to walk with. They are capable of being contracted or shortened: and it is only at the creature's moving that they are seen of their full length; at other times, no part of them is feen but the extremity of each, which is formed like a fort of button, being fomewhat larger than the rest of the horn.

Most of the species of asterias are found in the British feas. 1. The glacialis, with five rays, depressed, broad at the base, yellow, and having a round striated operculum on the back, is the most common; it feeds on oysters, and is very destructive to the beds. 2. The clathatra, or cancellated fea-star, with five short thick rays, hirfute beneath, cancellated above, is found with the former, but more rare. 3. The oculata, with five smooth rays, dotted or punctured, is of a fine purple colour, and is found about Anglesea. 4. The hispida, with five rays, broad, angulated at top, and rough with short briftles, is of a brown colour, and likewise found about Anglesea. 5. The placenta, with five very broad and membranaceous rays, extremely thin and flat, is found about Weymouth. 6. The fpherulata, with a pentagonal indented body; a small globular head between the base of each ray; the rays flender, jointed, taper, and hirfute on their fides; found off Anglesca. 7. The caput medulæ, or arborescent fea-ftar, with five rays iffuing from an angular body; the rays dividing into innumerable branches, growing flender as they recede from the base. These the animal, in fwimming, spreads like a net to their full length; and when he perceives any prey within them, draws them in again, thus catching it with all the dexterity of a fisherman. It is an inhabitant of every sea: and is called by some the Magellanic star-fish and basket-fish. When it extends its rays fully, it forms a circle of near three feet in diameter. The fragments of these rays furnish the fossil entrochi. If we drown this animal in brandy or spirits of wine, and keep the rays flat and expanded in the execution, it is eafy to extract by means of a pair of forceps the stomach of the animal whole and entire through the mouth. 8. The decacnemos, has ten very flender rays, with numbers of long beards on the fides; the body is small, and surrounded beneath with ten small filiform rays. It inhabits the western coasts of Scotland .- There are feveral other species mentioned by authors; some of them of 10, 12, 13, or even 14 rays.

Aristotle and Pliny called this genus usne, and Rella marina, from their refemblance to the pictured form of the flars of heaven; and they afferted that they were fo exceedingly hot, as inflantly to confume whatfoever they touched.

The fossil world has been greatly enriched by the fragments and remains of the several pieces of star-sish which have been converted into stones. See Aste. Afterial

See Aftracan ASTERIAS, the ancient name of the bittern.

ASTERISK, a mark in form of a star (*), placed over a word or fentence, to refer the reader to the margin, or elsewhere, for a quotation, explanation, or the

ASTERIUS, or Asturius, a Roman conful, in We have under his name, A Conference on the Old and New Testament, in Latin verse : in which each strophe contains, in the first verse, an historical fact in the Old Testament; and in the second, an application of that fact to some point in the New.

ASTERN, a fea phrase, used to fignify any thing at fome distance behind the ship; being the opposite of AHEAD, which fignifies the space before her. See

ASTEROPODIUM, a kind of extraneous fossil, of the same substance with the afterize or star-stones, to which they ferve as a base. See ASTERIA and STAR-

ASTHMA. See the Index subjoined to MEDICINE. ASTI, a city of Montferrat in Italy, feated on the Tanaro, and capital of the county of the same name. It is a bishop's see, and well fortified with strong walls and deep ditches; and is divided into the city, borough, citadel, and castle. There are a great many churches and convents, as well as other handfome buildings; and its territory is well watered, abounding with groves, pleafant hills, and spacious fields. It was taken by the French in 1745, and retaken by the king of Sardinia in 1746. E. Long. 8. 15. N. Lat. 54. 50.

ASTIGI (anc. geog.), a colony, and conventus juridicus, of Bætica, furnamed Augusta Firma, fituated on the Singulus, which falls into the Bætis; called alfo Colonia Afligitana (Pliny): Now Ecsa, midway between Seville and Corduba. W. Long. 5°. N. Lat. 37. 20.

ASTOMI, in anthropology, a people feigned with out mouths. Pliny speaks of a nation of Astomi in India who lived only by the fmell or effluvia of bodics taken in by the nose.

ASTORGA, a very ancient city of Spain, in the kingdom of Leon, with a bishop's see, is scated on the river Tuerta, and well fortified both by art and nature. It stands in a most agreeable plain, about 150 miles north-west of Madrid. There are excellent trouts in the river. W. Long. 6. 20. N. Lat 42. 20.

ASTRACAN, a province of Ruffia, and the most eafterly part of Europe; bounded on the north by Bulgaria and Baikiria; on the fouth by the Cafpian fea; on the west, by the Volga, which divides it from the Nagayan Tartars and Don Cossacks; and on the eaft, by the great ridge of mountains which part it from Great Tartary. The province extends from the 46th to the 52d degree of latitude. The fummer is long, and intenfely hot: the winter continues about three months so severe, that the Volga is frozen hard enough to bear loaded fledges. The foil is rich and fertile; but the Tartars who inhabit it are strangers to agriculture. On the western and southern sides of the Volga are heaths of a prodigious extent, fandy, defert, and uncultivated; these, however, produce vast quantities of fine transparent salt in pits, where the sun bakes and incruflates it to the thickness of an inch on the surface of

Maracan the water. There are pits in the neighbourhood of Aftracan which yield this excellent falt in such abundance, that any person may carry it off, paying at the gate of one farthing a pootl, which is equal to forty The metropolis, Astracan, is fituated within the boundaries of Asia, on an island called Dolgoi, about 60 English miles above the place where the Volga disembogues itself into the Caspian sea. The city derives its name from Hadgee Tarken, a Tartar, by whom it was founded. It was conquered by Iwan Bafilowitz, recovered by the Tartars in the year 1668, and retaken by the Czar, who employed for this purpose a great number of flut-bottomed vellels, in which he transported his forces down the Volga from Cafan.

The city of Aftracan is about two miles and a half in circumference, furrounded by a brick wall, which is now in a ruinous condition: but, if we comprehend the fuburbs, the circuit will be near five miles. The number of inhabitants amounts to 70,000, including Armenians and Tartars, as well as a few Persians and Indians. The garrifon confifts of fix reguments of the best Russian troops, who, when this place was alarmed from the fide of Persia, had in the adjacent plain erected a great number of small batteries, to scour the fields, and obstruct the approach of the enemy. The houses of Afracan are built of wood, and generally mean and inconvenient. The higher parts of the city command a prospect of the Volga, which is here about three miles in breadth, and exhibits a noble appearance. The marfly lands on the banks of it render the place very fickly in the funimer: the earth, being imprognated with falt, is extremely fertile, and produces abundance of fruit, the immoderate yie of which is attended with epidemical differences. Sickness is likewise the confequence of those annual changes in the atmofphere produced by the floods in fpring and autumn. All round the city of Ailracan, at the distance of two miles, are feen a great number of gardens, orchards, and vineyards, producing all forts of herbs an I roots. The grapes are counted fo delicious, that they are preserved in sand, and transported to court by land carriage at a prodigious expence; yet the wine of Aftracan is very indifferent. The fummer being generally dry, the inhabitants water their gardens by means of large wheels worked by wind or horfes, which raife the water to the highest part of the garden, from whence it runs in trenches to refresh the roots of every fingle tree and plant. The neighbouring country produces hares and partridges, plenty of quails in former, with wild and water fowl of all forts in abundance.

About ten miles below Astracan is a small island called Bosinaise, on which are built large storehouses for the falt, which is made about twelve miles to the cashward, and, being brought hither in boats, is conveyed up the Volga, in order to supply the country as far as Moscow and Twere. The quantity of falt animally dug for these purposes amounts to some million I pounds, the exclusive property of which is claimed the crown, and yields a confiderable revenue; it is iddentified bulk of the people live almost entire and and falt. The neighbourhood of these was as of great advantage to the fisheries. there is is of great advantage to the filheries,

to the fouth-east as far as Yaik, and even 100 miles Astracan. above Zaritzen. The principal fish here caught, are flurgeon and belluga. These, being silted, are put on board of veffels, and fent away in the fpring, for the use of the whole empire, even as far as Petersburg: but as fish may be kept fresh as long as it is frozen, the winter is no fooner fet in, than they transport great quantities of it by land through all the provinces of Russia. Of the roes of the fish called belluga, which are white, transparent, and of an agreeable flavour, the fifters here prepare the cavare, which is in fo much effect all over Europe. These difficules were fift established by one Tikon Demedost, a carrier, who fettled in this place about 60 years ago, his whole wealth confifting of two horfer. By dirt of skill and industry he soon grew the rickest merchant in this country: but his fueces became so allumne to the crown, that of late years it hath engroffed fome of the fisheries as well as the fait works.

From the latter end of July to the beginning of October, the country about Astracan is frequently infested with myriads of locusts, which darken the an in their progression from the north to the fouthward; and, wherever they fall, confume the whole verdure of the earth. These insects can even live for some time under water: for when the wind blows across the Volga. vast numbers of them fall in clusters, and are solled ashore; and their wings are no sooner dry, than they

rife and take flight agam.

Heretofore the inhabitants of Aftracan traded to Khuva and Bokhara; but at present these branches are loft, and their commerce is limited to Persia and the dominions of Russia. Even the trade to Persia is much diminished by the troubles of that country; nevertheless, the commerce of Altracan is ftill confiderable. Some years ago, the city maintained about 40 veffels, from 100 to 200 tons burden, for the Caspian traffic. Some of these belong to the government, and are offine manded by a commodore, under the direction of the admiralty. This office is generally well flocked with naval flores, which are fold occasionally to the merchants. The trading thips conver provisions to the frontier towns of Terkie and Killar, fituated on the Caspian sea ; and transport merchandise to several parts of Persia. The merchants of Astracan export to Persia, chiesty on account of the Armenians, red leather, linens, woolen cloths, and other European manufactures. In return, they import the commodities of Persia, particularly those manufactured at Casan; fuch as filk fashes intermixed with gold, for the use of the Poles; wrought filks and ituffs mixed with cotton; rice, cotton, rhubarb, and a small quantity of other drugs; but the chief commodity is raw filk. The government has engroffed the article of rhubarb, the greater part of which is brought into Russia by the Tartars of Yakutski, bordering on the Eastern Tartars belonging to China. They travel through Siberia to Samura, thence to Cafan, and lastly to Moscow. The revenue of Astracan is computed at 150,000 rubles, or 33,000 pounds, arising chiefly from falt and fish. The city is ruled by a governor, under the check of a chancery. He is nevertheless are bitrary enough, and exercises oppication with impunity. The officers of the admiralty and custom-house having

Agras very finall falaries, are open to corruption, and extremely rapacious. At christening fealls, which are attended Aftrantia with great intemperance, the guests drink a kind of cherry brandy out of large goblets; and every person invited throws a prefent of money into the bed of the mother, who fits up with great formality to be faluted by the company.

The Indians have a Pagan temple at Aftracan, in which they pay their adoration, and make offerings of fruit to a very ugly deformed idol. The priests of this paged afe incrute, beads, cups, and proftrations. The Taitars, on the contrary, hold idol worship in the ut-

most abomination.

ASTRÆA, in astronomy, a name which some give to the fign Virgo, by others called Erigone, and fometimes Ifis. The poets feign that juffice quitted heaven to relide on earth, in the golden age; but, growing weary of the iniquities of mankind, the left the earth, and returned to heaven, where the commenced a conffediation of ftars, and from her orb ftill looks down on the ways of men.

ASTRAGAL, in architecture, a little round moulding, which in the orders furrounds the top of the flaft or body of the column. It is also called the talon and tondino; it is used at the bottoms as well as tops of columns, and on other occasions: it properly represents a ring, on whatever part of a column it is placed; and the original idea of it was that of a circle of iron put round the trunk of a tree, used to support an edifice, to prevent its splitting. See Plate XXXIV. fig. 2. The aftragal is often cut into heads and herries, and is used in the ornamented entablatures to separate the several faces of the architrave.

ASTRAGAL, in gunnery, a round moulding encompassing a cannon, about half a foot from its mouth.

ASTRAGALOMANCY, a species of divination performed by throwing small pieces, with marks corresponding to the letters of the alphabet; the accidental disposition of which formed the answer required. This kind of divination was practifed in a temple of The word is derived from Hercules, in Achaia.

areayaxos, and mairia, divinition.

ASTRAGALUS, MILK VETCH, OF LIQUORICE verch: A genus of the decandria order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, Papilionacea. The pod is gibbous and bilocular. Of this genus there are 30 species. The common fort grows wild upon dry uncultivated places, and is recommended by Mr Anderson to be cultivated as proper food for cattle (fee AGRICULTURE, No 60, 61.) The other species deserving notice is the tragacantha, a thorny bush growing in Crete, Asia, and Greece, which yields the gum tragacanth. This is of so strong a body, that a drachm of it will give a pint of water the confidence of a fyrup, which a whole ounce of gum arabic is fearce sufficient to do. Hence its use for forming troches, and the like purpoles, in preference to the

ASTRAGALUS, in anatomy. See there No 65.

ASTRANTIA, MASTERWORT: A genus of the digyma order, belonging to the pentandria class of plants: and in the natural method ranking under the 45th order, Umbellate. The involucrum is lauceolated, open, equal, and coloured. The species are two, the

major and minor, both natives of the Alps, and pof. Aftriction folling no remarkable properties.

ASTRICTION, in law. Sec THIRLAGE.

Astriction, among physicians, denotes the operation of aftringent medicines.

ASTRINGENTS, in the materia medica, substances diffinguithed by a rough auftere taffe, and changing folutions of iron, especially those made in the vitriolic acid, into a dark purple or black colour; fuch are galls, tormentil root, biftort root, balaustines, terra japonica, acacia, &c. See MATERIA MEDICA.

ASTROGNOSIA, the science of the fixed stars, or the knowledge of their names, constellations, mag-

nitudes, Sc. Sec Astronomy.

ASTROITES, or STAR STONE, in natural history. See the articles Asteria and Star-stone; and Plate

ASTROLABE, the name for a stereographic projection of the sphere, either upon the plane of the equator, the eye being supposed to be in the pole of the world; or upon the plane of the meridian, when the eye is supposed in the point of the intersection of the equinoctral and horizon.

ASTROLABE is also the name of an instrument formerly used for taking the altitude of the sun or stars at fea.

ASTROLABF, among the ancients, was the fame as our armillary sphere.

ASTROLOGY, a conjectural science, which teaches to judge of the effects and influences of the flars, and to foretel future events by the fituation and different aspects of the heavenly bodies.

This science has been divided into two branches, nutural and judiciary. To the former belongs the pred Aing of natural events; as, the changes of weather, winds, ftorms, hurricanes, thunder, floods, earthquakes, &c. This art properly belongs to natural philosophy; and is only to be deduced a pofferiori, from phenomena and observations. Judiciary or judicial astrology, is that which pretends to foretel moral events; i. e. fuch as have a dependence on the free will and agency of man; as if they were directed by the flars. This art, which owed its origin to the practilers of knavery on credulity, is now univerfally exploded by the intelligent part of

The professors of this kind of astrology maintain. "That the heavens are one great volume or book, wherein God has written the history of the world; and in which every man may read his own fortune, and the transactions of his time. The art, say they, had its rife from the same hands as altronomy itself: while the ancient Affyrians, whose serene unclouded sky favoured their celeftial observations, were intent on tracing the paths and periods of the heavenly bodies, they difeovered a constant settled relation or analogy between them and things below; and hence were led to con-. clude thefe to be the Parce, the Destinies, for much talked of, which prefide at our births, and dispose of our future fate.

"The laws therefore of this relation being afcertained by a feries of observations, and the share each planet has therein; by knowing the precise time of any person's nativity, they were enabled, from their knowledge in altronomy, to creek a scheme or horoscope of the lituation of the planets at this point of time; and, .

Aftrology, bence, by confidering their degrees of power and in-Bronomy fluence, and how each was either strengthened or tempered by fome other, to compute what must be the refult thereof."

Thus the aftrologers .- But the chief province now remaining to the modern professors, is the making of

calendars or almanacks.

Judicial aftrology is commonly faid to have been invented in Chaldea, and thence transmitted to the Egyptians, Greeks, and Romans; though some will have it of Egyptian origin, and afcribe the invention to Cham. But it is to the Arabs that we owe it. At Rome the people were so infatuated with it, that the astrologers, or, as they were then called, the mathematicians, maintained their ground in spite of all the edicts of the emperors to expel them out of the city. See GE-NETHLIACI.

Add, that the Bramins, who introduced and practifed this art among the Indians, have hereby made themfelves the arbiters of good and evil hours, which gives them great authority: they are confulted as oracles; and they have taken care never to fell their answers

but at good rates.

The same superstition has prevailed in more modern ages and nations. The French historians remark, that in the time of Queen Catharine de Medicis, astrology was fo in much vogue, that the most inconsiderable

thing was not to be done without confulting the stars. Astronium And in the reign of King Henry III. and IV. of France the predictions of astrologers were the common theme of the court conversation. This predominant humour in that court was well rallied by Barclay. in his Argenis, Lib. II. on occasion of an astrologer, who had undertaken to instruct King Henry in the event of a war then threatened by the faction of the Guises.

ASTRONIUM, in botany: a genus of the pentandria order, belonging to the dicecia class of plants. The male calyx confilts of five leaves, and the corolla is quinquepetalous: Of the female the calyx and corolla are the same as in the male; the styli are three, and the feed is fingle. There is but one species, the graveolens, a native of Jamaica.

ASTRONOMICAL, fomething relating to A-

STRONOMY.

ASTRONOMICAL Calendar, an instrument engraved on copperplates, printed on paper, and pasted on a board, with a braft flider carrying a hair: it shows by inspection the fun's meridian altitude, right ascension, declination, rifing, fetting, amplitude, &c. to a greater degree of exactness than the common globes.

ASTRONOMICAL Sedor, a very useful mathematical instrument, made by the late ingenious Mr Graham; a description of which is given in the course of the

following article.

NOMY, RΟ

IS a knowledge of the heavenly hodies, with regard to their magnitudes, motions, diflances, &c. whether real or apparent; and of the natural causes on which their phenomena depend.

History of Astronomy.

The antiquity of this science may be gathered from what was spoken by the Deity at the time of creating the celestial luminaries, " Let them be for figns and feafons," &c.; whence it is thought probable that the human race never existed without some knowledge of aftronomy among them. Indeed, belides the motives of mere curiofity, which of themselves may be supposed to have excited people to a contemplation of the glorious celestial canopy, as far as that was possible, it is eafily to be seen that some parts of the science answer fuch effential purposes to mankind, that they could not possibly be dispensed with.

se underfood by Adam and he antedi-

By fome of the Jewish rabbins, Adam, in his state supposed to of innocence, is supposed to have been endowed with a knowledge of the nature, influence, and uses of the heavenly bodies; and Josephus ascribes to Seth and his posterity an extensive knowledge of astronomy. But whatever may be in this, the long lives of the antediluvians certainly afforded such an excellent opportunity for observing the celeftial bodies, that we cannot but suppose the science of astronomy to have been considerably advanced before the flood. Josephus fays, that longevity was bestowed upon them for the very purpose of improving the sciences of geometry and astronomy. The latter could not be learned in less than 600 years: so for that period (fays he) is the grand year." By

which it is supposed he meant the period wherein the fun and moon came again into the fame lituation as they were in the beginning thereof, with regard to the nodes, apogee of the moon, &c. "This period (lays Cassini), wherein we find no intimation in any monument of any other nation, is the finest period that ever was invented: for it brings out the folar year more exactly than that of Hipperchus and Ptolemy's and the lunar month within about one fecond of what is determined by modern aftronomers. If the antediluvians had fuch a period of 600 years, they must have known the notions of the fun and moon more exactly than their descendants knew them some ages after the flood."

On the building of the tower of Babel, Noah is sup-Aftronomic posed to have retired with his children born after the cal knowflood, to the north-eastern part of Asia, where his de-ledge of the feendants peopled the vast empire of China. "This Chinese. (fays Dr Long) may perhaps account for the Chinese having fo early cultivated the study of astronomy; their being so well settled in an admirable police, and continuing so many hundred years as they did in the worship of the true God." The vanity of that people Indeed has prompted them to pretend a knowledge of aftronomy almost as early as the flood itself. Some of the Jesuit missionaries have found traditional accounts among the Chinese, of their having been taught this science by their first emperor Fo-hi, supposed to be Noah; and Kempfer informs us, that this personage discovered the motions of the heavens, divided time into years and months, and invented the twelve figns into which they divide the zodiac, which they diffinguish by the following

following names. 1. The moufe. 2. The ox or cow. Their 3. The tiger. 4. The hare. 5. The dragon. 6. The mance for deepent. 7. The horfe. 8. The fleep. 9. The monkey. the zodiac. 10. The cock or hen. 11. The dog; and, 12. The boar. They divide the heavens into 28 constellations, four of which are affigned to each of the feven planets: fo that the year always begins with the fame planet: and their confiellations answer to the 28 mansions of the moon used by the Arabian astronomers. These conftellations in the Chincfe books of aftronomy, are not marked by the figures of animals, as was in use among the Greeks, and from them derived to the other European nations, but by connecting the stare by straight lines: and Dr Long informs us, that in a Chinese book in thin 4to, shown him by Lord Pembroke, the thars were represented by small cucles joined by lines; to that the Great Bear would be marked thus:

To the emperor Hong-ti, the grandfon of Noah, they attribute the discovery of the pole-star, the invention of the mariner's compals, of a period of 60 years, and some kind of sphere. This extraordinary antiquity, however, is with good reason suspected, as is likewife their knowledge in the calculation of eclipses; of which Du Halde assures us, that 36 are recorded by Confucius himself, who lived 551 years before Christ; and P. Trigault, who went to China in 1619, and read more than too volumes of their annals, fays, " It is certain that the Chinese began to make astronomical observations soon after the flood; that they have obferved a great number of eclipses, in which they have noted down the hour, day, month, and year, when they happened, but neither the duration nor the quantity; and that these eclipses have been made use of for regulating their chronology."

But out of this abundance (fays Dr Long), it is much to be regretted, that so very few of their observations have been particularized; for befide what has been mentioned above, we meet with no very ancient observations of the Chinese, except a winter solftice in the year 1111, and a fummer folitice in the year 882 before Christ. Martini indeed speaks of a summer solflice 2342 years before that period. But M. Cassini, who calculated it, found that there must have been an error in the Chinele computation, of 500 years at leaft. An error of equal magnitude appears to have been committed in the conjunction of the five planets, which it is pretended they observed between the years 2513 and 2435 before Chrift. In fhort, some have suppofed, that none of these are real observations, but the refult of bungling calculatious; and it has been hinted, but furely on too flight a foundation, that even those good fathers themselves were greatly to be suspected. But let us come to things which are not contested.

"P. Gaubil informs us, that at least 120 years before Christ, the Chinese had determined by observation the number and extent of their confiellations as they now stand; the situation of the fixed stars with respect to the equinoctial and folfitial points; and the obliquity of the ecliptic. He farther fays, he cannot tell by what means it is that they foretel eclipses: but this is certain, that the theory by which they do predict

them, was fettled about the same time; and that they were acquainted with the true length of the folar year, the method of observing meridian altitudes of the fun by the shadow of a gnomon, and of learning from thence his declination and the height of the pole, long before. We learn, moreover, from the fame missionary, that there are yet remaining among them fome treatifes of astronomy, which were written about 200 years before Christ; from which it appears, that the Chinese had known the daily motion of the sun and moon, and the times of the revolutions of the planet; many years before that period.

"We are informed by Du Halde, that, in the province of Honan, and city Teng-foang, which is nearly in the middle of China, there is a tower, on the top of which it is faid that Tcheou-cong, the most skalful astronomer that ever China produced, made his observations. He lived 1200 years before Ptolemy, or more than 1000 years before Christ, and passed whole nights in observing the celestial bodies, and arranging them into constellations. He used a very large brass table placed perfectly horizontal, on which was fixed a long upright plate of the fame metal, both of which were divided mto degrees, &c. By these he marked the mendian altitudes; and from thence derived the time of the fol-

flices, which were their principal epocha."

Dr Long represents the flate of altronomy in China as at prefent very low; occasioned, he says, principally by the barbarous decree of one of their emperorst, to have all the books in the empire burnt, (See Gara excepting fuch as related to agriculture and medicine. We are informed, however, by the Abbé Grofier, in his description of China, that astronomy is cultivated in Peking in the same manner as in most of the capital cities in Europe. A particular tribunal is established there, the jurisdiction of which extends to every thing relating to the observation of celestial phenomena. Its members are, an infpector; two pre'idents, one of them a Tartar and the other a Chinese; and a certain number of mandarines who perform the duty of affestors; but for near a century and a hand the place of the Chincse president has been filled by an European. Since that time particular attention has been paid to the inflruction of the aftronomical pupils; and the prefidents have always confidered it as their duty to make them acquainted with the fyslem and method of calculation made use of in Europe. Thus two thirds of the aftronomical pupils maintained at the emperor's expence, in all about 200, have a tolerable notion of the flate of the heavens, and understand calculation fo well as to be able to compose ephemerides of sufficient exactness. The missionaries have never been the authors of any of these ephemerides: their employment is to revise the labours of the Chinele mathematicians, verify their calculations, and conrect any errors into which they have fallen. The Portuguele mission still continues to furnish altronomers for the academy as it did at the first.

The astronomical tribunal is subordinate to that of ceremonies. When an eclipfe is to be observed, information must be given to the emperor of the day and hour, the part of the heavens where it will be, &c. and this intelligence must be communicated fome months before it happen: the cclipfe must also be calculated for the longitude and latitude of the capital city of

every province of the empire. These observations, as well as the diagram which reprefents the eclipfe, are preferred by the tribunal of ceremonies, and another called the calao, by whom it is transmitted to the different provinces and cities of the empire. Some days before the eclipse, the tribunal of ceremonics causes to be fixed up in a public place, in large characters, the hour and minute when the eclipse will commence; the quarter of the heavens in which it will be visible, with the other particulars relating to it. The mandarins are fummoned to appear in state at the tribunal of astronomy, and to wait there for the moment in which the phenomenon will take place. Each of them carries in his hand a fleet of paper, containing a figure of the eclipfe and every circumflauce attending it. As foon as the observation begins to take place, they throw themselves on their knees, and knock their heads against the earth, and a horrid noise of drums and cymbals immediately commences throughout the whole city: a ceremony proceeding from an ancient superstitious notion, that by fuch noise they prevented the luminary from being devoured by the celeftial dragon; and though this notion is now exploded in China, as well as everywhere elfe, fuch is the attachment of the people to ancient cultums, that the ceremonial is flill preferved. While the mandarins thus remain profirated in the court, others, stationed on the observatory, examine, with all the attention possible, the beginning, middle, and end of the eclipse, comparing what they observe with the figure and calculations given. They then write down their observations, affix their feal to them, and transmit them to the emperor; who on his part has been no lefs affiduous to observe the eclipse with accuracy. A ceremonial of this kind is observed throughout the whole empire.

The Japonele, Siamele, and inhabitants of the Mogul's empire, have also, from time immemorial, been acquanted with aftronomy; and the celebrated observatory at BENARES, is a monument both of the ingenuity of the people and of their skill in this science.

Mr Bailly has been at great pains to investigate the progress of the Indians in astronomical knowledge, and gives a splendid account of their proficiency in the science, as well as of the antiquity of their observations. He has examined and compared four different aftronomical tables of the Indian philosophers. 1. Of the Siamele, explained by M. Caffini in 1689. 2. Those brought from India by M. le Gentil of the Academy of Sciences. 3. and 4. Two other manuscript tables. found among the papers of the late M. de Liste. All of these tables have different epochs, and differ in form, being also constructed in different ways; yet, they all evidently belong to the fame aftronomical fyflem : the motions attributed to the fun and the moon are the same and the different epochs are so well connected by the mean motions, as to demonstrate that they had only one, whence the others were derived by calculation. The meridians are all referred to that of Benarcs above mentioned. The fundamental epoch of the Indian astronomy is a conjunction of the sun and moon, which took place at no less a distance of time than 3102 years before the Christan era. Mr Bailly informs us, that, according to our most accurate astronomical tables, a conjunction of the fun and moon acsually did happen at that time. But though the bra-

mins pretend to have afcertained the places of the two luminaries at that time, it is impossible for us at this time to judge of the truth of their affertions, by reason of the unequal motion of the moon; which, as shall afterwards be more particularly taken notice of, now performs its revolution in a shorter time than formerly.

Our author informs us, that the Indians at prefent calculate eclipses by the mean motions of the fun and moon observed 5000 years ago; and with regard to the solar motion, their accuracy far exceeds that of the best Grecian aftronomers. The lunar motions they had also fettled by computing the space through which that luminary had passed in 1,600,984 days, or somewhat more than 4383 years. They also make use of the cycle of 19 years attributed by the Greeks to Meton; and their theory of the planets is much better than that of Ptolemy, as they do not suppose the earth to be the centre of the celeftial motions, and they believe that Mercury and Venus turn round the fun. Mr Bailly also informs us, that their astronomy agrees with the most modern discoveries of the decrease of the obliquity of the ecliptic, the acceleration of the motion of the equinoctial points, with many other particulars too tedious to enumerate in this place.

It appears also, that even the Americans were not Astronomy unacquainted with aftronomy, though they made use Americana only of the folar, and not of the lunar rections, in their division of time. The Mexicans have had a strange predilection for the number 13. Their shortest periods confilted of 13 days; their cycle of 13 months, each containing 20 days; and their century of four periods of 13 years each. This excessive veneration for the number 13, according to Siguenza, arose from its being supposed the number of their greater gods. What is very surprising, though afferted as a fact by Abbé Clavigero, is, that having discovered the excels of a few hours in the folar above the civil year, they made use of intercalary days, to bring them to an equality; but with this difference in regard to the method established by Julius Cæsar in the Roman kalendar, that they did not interpole a day every four years, but 13 days (making use here even of this favourite number) every 52 years, which produces the fame regulation of time.

Among those nations who first began to make any Of the figure in ancient history, we find the Chaldeans and Chaldeans Egyptians most remarkable for their astronomical and Egypknowledge. Both of them pretended to an extrava-tians. gant antiquity, and disputed the honour of having been thefirst cultivators of the science. The Chaldeans boasted of their temple of Belus; and of Zoroafter, whom they placed 5000 years before the destruction of Troy: the Egyptians boalled of their colleges of priefls, where aftronomy was taught; and of the monument of Ofymandyns, in which we are told was a golden circle 365 cubits in circumference and one cubit thick. The upper face was divided into 365 equal parts, answering to the days of the year; and on every division were written the name of the day, and the heliacal rifing of the feyeral flars for that day, with the prognoffications from their rifing, principally, as Long conjectures, for the weather.

The Chaldcans certainly began to make observations very foon after the confusion of languages; for when Alexander the Great took Babylon, Califthenes,

Indian aftronomy.

by his order, inquired after the astronomical observations recorded in that city, and obtained them for 1903 years back. Nothing however, now remains of the Chaldean altronomy, excepting some periods of years which they had formed for the more ready computation of the heavenly bodies. But though they must have laboured under great disadvantages, for want of proper instruments, in those early ages, Gemina, as quoted by Petavius in his Uranologion, informs us, that they had determined, with tolerable exactness, the length both of a fynodical and periodical month. They had also discovered, that the motion of the moon was not uniform, and even attempted to affign those parts of her orbit in which it was quicker or flower. Ptolemy also assures us, that they were not unacquainted with the motion of the moon's nodes, and that of her apogee, supposing that the former made a complete revolution in 6585 days, or 18 years 15 days and 8 hours; which period, containing 223 complete lunations, is called the Chaldean Saros. The fame author also gives us, from Hipparchus, several observations of lunar eclipses which had been made at Babylon about 720 years before Christ; but though he might very probably meet with many of a more ancient date, it was impossible to mention them particularly, on account of the most imperfect state of the Chaldean chronology. which commenced only with the era of Nabonassar, 747 years before Christ. Aristotle likewise informs us, that they had many observations of the occultations of fixed stars and planets by the moon; and from hence, by a very natural and easy inference, they were led to conclude that the ecliples of the fun were occasioned also by the moon, especially as they constantly happened when the latter was in the same part of the heavens with the fun. They had also a considerable share in arranging the stars into constellations. Nor had the comets, by which aftronomers in all ages have been fo much perplexed, escaped their observation; for both Diodorus Siculus and Appollinus Myndius, in Seneca, inform us, that many of the Chaldeans held these to be lasting bodies, which have stated revolutions as well as the planets, but in orbits vastly more extensive; on which account they are only feen by us while near the earth, but disappear again when they go into the higher regions. Others of them were of opinion, that the comets were only metcors raised very high in the air, which blaze for a while, and disappear when the matter of which they confilt is confumed or dispersed. Dialing was also known among them long before the Greeks were acquainted with any fuch thing.

It is evident, indeed, that the countries both of Chaldea and Egypt were exceedingly proper for aftronomical obtevations, on account of the general puribelus, which was f an extraordinary height, with thairs winding round, up to the top, is supposed to have been an astronomical observatory; and the lofty pyramids of Egypt, with the pyramids of Egypt, whitever they were originally deligned for, might possible ver they were originalpole. Indeed these very ancientifiwer the same purskill of this people in practical assenuments show the all fituated with their four fronts exy, as they are cardinal points. Herodotus ascribes v facing the knowledge in astronomy to Sefostris, whon gyptian Vol. II. Part II.

Newton makes cotemporary with Solomon: but if this was the case, he could not be the instructor of the Egyptians in altronomical matters, fince we find that Mofes, who lived 500 years before Solomon, was shalled in all the wildom of the Egyptians, in which we are undoubtedly to include aftronomy.

From the tellimony of fome ancient authors, we learn that they believed the earth to be spherical, that they knew the moon was eclipfed by falling into its fladow, and that they made their observations with the greatest exactness. They even pretended to foretel the appearance of comets, as well as earthquakes and inundations; which extraordinary knowledge is likewife ascribed to the Chaldeans. They attempted to meafure the magnitude of the earth and fun; but the methods they took to find out the latter were very erroneous. It does not indeed appear with certainty that they had any knowledge of the true tyftem of the un:verse; and by the time of the emperor Augustus, their aftronomical knowledge was entirely loft.

From Chaldea the ference of adronomy most probably Of the Pho paffed into Phenicia; though fome are of opinion that means. the Phenicians derived their knowledge of this science from the Egyptians. They feem, however, to have been the first who applied astronomy to the purpose, of navigation; by which they became matters of the fea, and of almost all the commerce in the world. They became adventurous in their voyages, fleering their ships by one of the stars of the Little Bear; which being near the immoveable point of the heavens called the Pole, is the most proper guide in navigation. Other nations made their observations by the Great Bear; which being too diffant from the pole could not guide them in long voyages; and for this reason they never durst venture far from the coasts.

The first origin of astronomical knowledge among Astronomy the Greeks is unknown. Sir Isaan Newton supposes of the that most of the constellations were invented about Greeks. the time of the Argonautic expedition: but Dr Long is of opinion that many of them must have been of a much older date; and that the shepherds, who were certainly the first observers, gave names to them according to their fancy; from whence the poets invented many of their fables. Several of the conftellations are mentioned by Hefiod and Homer, the two molt ancient writers among the Greeks, who lived about 870 years before Christ; Hesiod desiring the farmer to regulate the time of fowing and harvest by the rifing and fetting of the Pleiades; and Honer informing us, that observations from the Pleiades, Orion, and Arcturus, were used in navigation. Their astronomi-Improved cal knowledge, however, was greatly improved by by Thales Thales the Milesian, who travelled into Egypt, and brought from thence the first principles of the science. He is faid to have determined the height of the pyramids by measuring their shadows at the time the fun was 45 degrees high, and when of confequence the lengths of the shadows of objects are equal to their perpendicular heights. But his reputation was raifed to the highest pitch among his countrymen, by the prediction of an echple, which happened just at the time that the armies of Alyattes king of Lydia, and Cyaxares the Mede, were about to engage; and being regarded as an evil omen by both parties, inclined them

to peace. To him Callimachus attributes the forming of the confiellation of the Little Bear; the knowledge of which he certainly introduced into Greece. He also taught the true length of the year; determined the cosmical setting of the Pleiades in his time to have been 25 days after the autumnal equinox; divided the carth into five zones by means of the polar circles and tropics; taught the obliquity of the ecliptic; and showed that the equinoctial is cut by the meridians at right angles, all of which interfect each other at the poles. He is also said to have observed the exact time of the folflices, and from thence to have deduced the true length of the folar year; to have observed eclipses of the fun and moon; and to have taught that the moon had no light but what she borrowed from the sun. According to Stanley, he also determined the diameter of the fun to be one-720th part of his annual orbit. "But (fays Dr Long) thefe things should be received with caution. There are fome reasons which might be affigned for supposing that the knowledge of Thales in these matters was much more circumscribed: and indeed it is not unreasonable to suppose, that that veneration for the ancients which leads authors to write profesfedly on the history of ancient times, may have induced them to atcribe full as much knowledge to them who lived in them as was really their due."

By Anaximunder.

Doctrines of Pythagoras.

The fuccessors of Thales, Anaximander, Anaximenes, and Anaxagoras, contributed confiderably to the advancement of astronomy. The first is faid to have invented or introduced the gnomon into Greece; to have observed the obliquity of the ecliptic; and taught that the earth was ipherical, and the centre of the universe, and that the fun was not less than it. He is also faid to have made the first globe, and to have fet up a fun-dial at Lacedemon, which is the fuft we hear of among the Greeks; though fome are of opinion that these pieces of knowledge were brought from Babylon by Pherycides, a cotemporary of Anaximander. Anaxagoras also predicted an eclipse which happened in the lifth year of the Peloponnefian war; and taught that the moon was habitable, confisting of hills, valleys, and waters, like the earth. His cotemporary Pythagoras, however, greatly improved not only aftronomy and mathematics, but every other branch of philofophy. He taught that the universe was composed of four elements, and that it had the fun in the centre; that the earth was round, and had antipodes; and that the moon reflected the rays of the fun; that the stars were worlds, containing earth, air, and ether; that the moon was inhabited like the earth; and that the comets were a kind of wandering stars, disappearing in the superior parts of their orbits, and becoming visible only in the lower parts of them. The white colour of the milky way he atcribed to the brightness of a great number of small stars; and he supposed the distances of the moon and planets from the earth to be in certain harmonic proportions to one onother. He is faid also to have exhibited the oblique course of the fun in the ecliptic and the tropical circles, by means of an artificial fphere; and he first taught that the planet Venus is both the evening and morning star. This philosopher is faid to have been taken prisoner by Cambytes, and thus to have become acquainted with all the mysteries of the Persian magi; after which he fettled at Crotona in Italy, and founded the Italian feet.

About 440 years before the Christian era, Philolaus, a celebrated Pythagorean, afferted the annual motion of the earth round the fun; and foon after Hicetas, a Syracufan, taught its diurnal motion on its own axis. About this time also flourished Meton and Euctemon at Athens, who took an exact observation of the summer folftice 432 years before Christ; which is the oldest observation of the kind we have, excepting what is delivered by the Chinese. Meton is faid to have composed a cycle of 19 years, which still bears his name; and he marked the rifings and fettings of the stars, and what feafons they pointed out: in all which he was affifted by his companion Euclemon. The science, however, was obscured by Plato and Aristotle, who embraced the fyftem afterwards called the Ptolemaic, which places the earth in the centre of the universe.

Eudoxus the Cnidian was a cotemporary with Aristotle, though confiderably older, and is greatly celebrated on account of his skill in astronomy. He was the first who introduced geometry into the science, and he is supposed to be the inventor of many propositions attributed to Euclid. Having travelled into Egypt in the earlier part of his life, and obtained a recommendation from Agefilaus to Nectanebus king of Egypt, he, by his means, got access to the prickt, who had the knowledge of attronomy entirely among them, after which he taught in Afia and Italy. Seneca tells us that he brought the knowledge of the planetary motions from Egypt into Greece; and Archimedes, that he believed the diameter of the fun to be nine times that of the moon. He was also well acquainted with the method of drawing a fun dial upon a plane: from whence it may be inferred that he understood the doctrine of the projection of the sphere: yet, notwithstanding what has been faid concerning the observations of Eudoxus, it is not certain that his fphere was not taken from one much more ancient. afcribed to Chiron the Centaur. The reason given for this supposition is, that had the places of the stars been taken from his own observations, the constellations must have been half a sign farther advanced than they are faid to be in his writings.

Soon after Eudoxus, Calippus flourished, whose syflem of the celeftial sphere is mentioned by Aristotle: but he is better known from a period of 76 years, containing four corrected Metonic periods, and which had its beginning at the fummer folftice in the year 330 before Christ. But about this time, or rather earlier, the Greeks having begun to plant colonies in Italy, Gaul, and Egypt, these became acquainted with the Pythagorean fystem, and the notions of the ancient Druids concerning astronomy. Julius Caster informs us, that the latter were skilled in this science; and that the Gauls in general were able failor which at that

all those who cultivated them; and this school continued to be the feminary of all kinds of literature, till the invalion of the Saracers in 650. Timocharis and Arythillus, who first cultivated the astronomical science in this school, began to put it on a new footing; being much more careful in their observations, and exact in noting down the times when they were made, than their predeceflors. Ptolemy affores us, that Hipparchus made use of their observations, by means of which he discovered that the stars had a motion in longitude of about one degree in a hundred years; and he cites many of their observations, the oldest of which is before the erection of this school, in the year 205, when the moon just touched the northern star in the forehead of the Scorpion; and the latt of them was in the 13th year of Philadelphus, when Venus Ind the former flar of the four in the left wing of Vingo.

From this time the feience of altronomy continued greatly to advance. Ariftarchus, who lived about 270 years before Christ, strenuously afferted the Pythagorean fyllem, and gave a method of determining the diflance of the fun by the moon's dichotomy. Eratofthenes, born at Cyrene in 271 B. C. determined the measure of a great circle of the earth by means of a gnomon. His reputation was fo great, that he was invited from Athens to Alexandria by Ptolemy Energetes, and made by him keeper of the royal library at that place. At his infligation the same prince let up those armillas or spheres, which Hipparchus and Ptolemy the aftionomer afterwards employed to fuccefsfully in observing the heavens. He also found the distance between the tropics to be eleven fuch parts as the whole meridian contains eighty-three. About the fame time Berofus, a native of Chaldea, flomished at Athens. He is by fome faid to have brought many obfervations from Babylon, which are afcribed to the Greeks; while others contend, that the latter owe little or nothing of their aftronomical knowledge to Discoveries the Babylonians. The celebrated Archimedes, who next to Sir Isaac Newton holds the first place among mathematicians, was nothing inferior as an aftronomer to what he was as a geometrician. He determined the distance of the moon from the earth, of Mercury from the moon, of Venus from Mercury, of the fun from Venus, of Mars from the fun, of Jupiter from Mars, and of Saturn from Jupiter; as likewise the diflance of the fixed stars from the orbit of Saturn. That he made altronomical observations, is not to be doubt-G; and it appears from an epigram of the poet Claudian, that he invented a kind of planetarium, or orrery, to reputent the phenomena and motions of the heavenly bou .g.

Of Hippar-

of Archi-

medes.

Hipparcha was the first who applied himself to the fludy of every prt of altronomy, his predeceffors havthe fun and moon. colemn also informs us, that he first discovered the orbor of the planets to be eccentric, and on this hypothem grote a book against Eudoxus and Calippus. He gi many of his observa-tions; and says, that by company one of his with another made by Ariffarchus in one of his with was enabled to determine the length ears before, he great precision. Hipparchus also sirst the year with anticipation of the moon's nodes, the eccl out the her orbit, and that she moved slower in heirity of

than in her perigee. He collected the accounts of fuch ancient eclipses as had been observed by the Chaldeans and Egyptians. He formed hypotheles concerning the celestial motions, and constructed tables of those of the fun and moon, and would have done the fame with those of the other planets, if he could have found ancient observations sufficient for the purpose; but, thefe being wanting, he was obliged to content bimfelf with collecting fit observations for that purpose, and endeavouring to form theories of the five planets. By comparing his own observations on the Spica Virgihis with those of Timochares at Alexandria made 160 years before, he discovered that the fixed stars changed their places, and had a flow motion of their own from well to call. He corrected the Calippic period, and pointed out some errors in the method laid down by Eratofthenes for meafuring the circumference of the earth. By means of geometry, which was now greatly improved, he was enabled to attempt the calculation of the fun's diffance in a more correct manner than any of his predecessors; but unhappily it required to much accuracy in observation as was found impracticable. His greatest work, however, was his catalogue Mikes the of the fixed flars, which he was induced to attempt fift cotaby the appearance of a new star. The catalogue is pre-logue clins-ferved by Ptolemy, and contains the longitudes and latitudes of 1022 flars, with their apparent magintudes. He wrote also concerning the intervals between the ecliples both folar and lunar, and is faid to have calculated all that were to happen for no lefs than 600 years from his time.

Little progress was made in astronomy from the time System of of Hipparchus to that of Ptolemy, who flourished Ptolemy. in the first century. The principles on which his fyftem is built are indeed erroneous; but his work will always be valuable on account of the number of ancient observations it contains. It was first translated out of the Greek into Arabic in the year 827, and into Latin from the Arabic in 1230. The Greek original was unknown in Europe till the beginning of the 15th century, when it was brought from Conflantinople. then taken by the Turks, by George a monk of Trapezond, who translated it into Latin. Various edition. were afterwards published; but little or no improvement was made by the Greeks in this feience.

During the long period from the year 800 to the Afronces beginning of the 14th century, the wellern parts of of the Aca-Europe were immerfed in deep ignorance and barban-hams. ty. However, feveral learned men arose among the Arabians. The caliph Al Manfur was the first who introduced a tafte for the iciences in his empire. His grandfon Al Mamun, who afcended the throne in 814, was a great encourager of the sciences, and devoted much of his own time to the fludy of them. He made many aftronomical observations himself, and determined the obliquity of the ecliptic to be 23° 35'. He employed many able mechanics in constructing proper instruments, which he made use of for his observations; and under his auspices a degree of the earth was meafured a fecond time in the plain of Singar, on the border of the Red fea. From this time altronomy was fludiously cultivated by the Arabians; and Elements of Allronomy were written by Alferganus, who was partly cotemporary with the caliph Al Mainun. But the most celebrated of all their astronomers is Albateg-

3 G 2

nius.

nius, who lived about the year of Christ 880. He greatly reformed aftionomy, by comparing his own ob-fervations with those of Ptolemy. Thus he calculated the motion of the fun's apogee from Ptolemy's time to his own; determined the precession of the equinoxes to be one degree in 70 years; and fixed the fun's greatest declination at 23.35'. Finding that the tables of Ptolemy required much correction, he composed new ones of his own fitted to the meridian of Aracta, which were long held in estimation by the Arabians. After his time, though several eminent astronomers appeared among the Saracens, none made any very valuable observations for several centuries, excepting Ebn Younis astronomer to the caliph of Egypt, who obferved three eclipses with such care, that by means of them we are enabled to determine the quantity of the moon's acceleration fince that time.

Other eminent Saracen altronomers were, Arzachel a Moor of Spain, who observed the obliquity of the celiples, and confiructed tables of fines, or half chords of double arcs, dividing the diameter into 300 parts; and Alhazen, his cotemporary, who first showed the importance of the theory of refractions in aftronomy; writing also upon the twilight, the heights of the clouds, and the phenomenon of the horizontal moon.

Ulug Beg, a grandson of the famous Tartar prince Timur Beg, or Tamerlane, was a great proficient in practical aftronomy. He is faid to have had very large instruments for making his observations; particularly a quadrant as high as the church of Sancta Sophia at Constantinople, which is 180 Roman feet. He composed astronomical tables from his own observations for the meridian of Samarcand his capital, so exact as to differ very little from those afterwards constructed by Tycho Brahe; but his principal work is his catalogue of the fixed stars, made from his own observations in the year of Christ 1437. The accuracy of his observations may be gathered from his determining the height of the pole at Samarcand to be 39° 37' 23".

Besides these improvements, we are indebted to the Arabians for the present form of trigonometry. Menelaus, indeed, an eminent Greek ailronomer, who flourished about the year 90, had published three books of Spherics, in which he treated of the geometry neceffary to aftronomy, and which show great skill in the feiences; but his methods were very laborious, even after they had been improved and rendered more simple by Ptolemy: but Geber, the Arabian, inflead of the ancient method, proposed three or four theorems, which are the foundation of our modern trigonometry. The Arabians also made the practice still more simple, by using sines instead of the chords of double arcs. The arithmetical characters they had from the Indians.

During the greatest part of this time, almost all Euconomy rope continued ignorant not only of aftronomy but of Europe, every other science. The emperor Frederic II. first began to encourage learning in 1230; restoring some univerfities, and founding a new one in Vienna. He also caused the works of Aristotle, and the Almageit or Astronomical Trestise of Ptolemy, to be translated

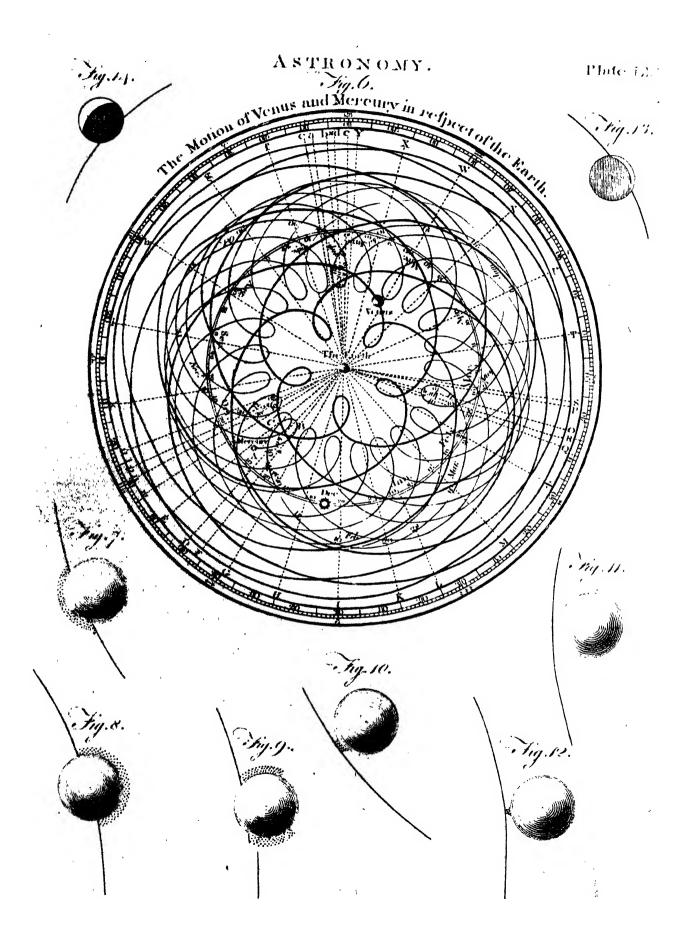

Latin; and from the translation of this book we date the revival of astronomy in Europe. Two years r its publication, John de Sacro Bosco, or of Hax, an Englishman, wrote his four books De Sphera, nich he compiled from Ptolemy, Albategnius, Alfer-

ganus, and other Arabian astronomers: this work was fo much celebrated, that for 300 years, it was preferred in the schools to every other; and has been thought worthy of feveral commentaries, particularly by Clavius in 1531. In 1240, Alphonfo king of Castile caused the tables of Ptolemy to be corrected: for which purpose he affembled many persons skilled in aftronomy, Christians, Jews, and Moors; by whom the tables called Alphonsine were composed at the expence of 40,000, or according to others 400,000 ducats. About the same time, Roger Bacon, an English monk, published many things relative to astronomy; particularly of the places of the fixed flars, folar rays, and lunar aspects. Vitellio, a Polander, wrote a treatife on Optics about 1270, in which he showed the use of refractions in altronomy.

From this time to that of Purbach, who was born improvein 1423, few or no improvements were made in aftro-ments of nomy. He wrote a commentary on Ptolemy's Al-Purbach. magell, fome treatifes on Arithmetic and Dialling, with tables for various climates. He not only used fpheres and globes, but constructed them himself; and formed new tables of the fixed flars, reduced to the middle of that age. He composed also new tables of fines for every ten minutes, which Regiomontanus afterwards extended to every fingle minute, making the whole fine 60, with 6 cyphers annexed. He likewife corrected the tables of the planets, making newsequations to them, because the Alphonine tables were very faulty in this respect. In his solar tables he placed the fun's apogee in the beginning of Cancer; but retained the obliquity of the ecliptic 23° 334', to which it had been reduced by the latest observations. He made new tables for computing ecliples, of which he observed some, and had just published a theory of the planets, when he died in 1461.

John Muller of Monteregio (Coningherg), a town of Region of Franconia, from whence he was called Regiomentanus, montanus, was the scholar and successor of Purbach. He completed the epitome of Ptolemy's Almagest which Purbach had begun: and after the death of the latter, went to Rome, where he made many astronomical obfervations. Having returned to Nuremberg in 1471, he was entertained by a wealthy citizen named Bernard Walther, who having a great love for astronomy, caused feveral instruments to be made under the direction of Regiomontanus, for observing the altitudes of the fun and stars, and other celestial phenomena. Among thefe was an armillary aftrolabe, like that which had been used by Hipparchus and Ptolemy at Alexandria. and with which many observations were made. He also made ephemerides for 30 years to come showing the linations, eclipses, &c. He wrote the Theory of the Planets and Comets, and a Treatiff of Triangles the Planets and Comets, and a Treative cases. He is yet in repute for several extraordidry cases. He is said to have been the first who is oduced the use of to have published in tangents into trigonometry ing been lately invented) print (the art of printing most celebrated ancient the works of many of death, which happened at aftronomers. After a diligent fearch for all his in-Rome, Walther Is which could be found: and construments and Fations with the instruments he had till tinued his of he observations of both were collected his death the fenate of Nuremberg, and published by ord

18 vival of

there by John Schoner in 1544; afterwards by Snellius at the end of the observations made by the landgrave of Hesse in 1618; and lastly, in 1666, with those of Tycho Brahe. Walther, however, as we are told by Snellius, found fault with his armilla, not being able to give any observation with certainty to less than ten minutes. He made use of a good clock, which also was a late invention in those days.

Of Werner.

John Werner, a clergyman, fucceeded Walther as altronomer at Nuremberg; having applied himfelf with great affiduity to the fludy of that feience from his infancy. He observed the motion of the comet in 1500; and published feveral tracts, in which he handled many capital points of geometry, aftronomy, and geography, in a mafferly manner. He published a translation of Ptolemy's Geography, with a commentary, which is fill extant. In this he first proposed the method of finding the longitude at fea by observing the moon's diffance from the fixed flars; which is now fo foccefsfully put in practice. He also published many other treatifes on mathematics and geography; but the most remarkable of all his treatises are those concerning the motion of the eighth splicre or of the fixed itars, and a flort theory of the same. In this he showed, by comparing his own observations of the flars Regulus, Spica Virginis, and the bright ftar in the southern scale of the Balance, made in 1514, with the places affigned to the same stars by Ptolemy, Alphonius, and others, that the motion of the fixed flars, now called the precession of the equinoctial points, is one degree ten minutes in 100 years, and not one degree only, as former astronomers had made it. He made the obliquity of the ecliptic 23° 28', and the first star of Aries 26° distant from the equinoctial point. He also constructed a planetarium representing the celestial motions according to the Ptolemaic hypothefis, and made a great number of meteorological obferrations with a view towards the prediction of the weather. The obliquity of the ecliptic was fettled by Dominic Maria, the friend of Copernicus, at 23° 29', which is still held to be just.

The celebrated Nicolaus Copernicus next makes his rean lystem appearance, and is undoubtedly the great reformer of restored by the astronomical science. He was originally bred to the Copernicus practice of medicine, and had obtained the degree of Doctor in that faculty; but having conceived a great regard for the mathematical fciences, especially astronomy, he travelled into Italy, where he for some time was taught by Dominic Maria, or rather affilled him in his aftronomical operations. On his return to his own country, being made one of the canons of the church, he applied himself with the utmost assiduity to the contemplation f the heavens, and to the fludy of the celeftial motion: He foon perceived the deficiency of all the hypotheses us which it had been attempted to acthe hypothetes be which it had been attempted to account for these moting; and for this reason he set himfelf to study the work; sethe ancients, with all of whom he also was distaisted compling Pythagoras; who, as has been already related, leed the sum in the centre, and supposed all the places, with the earth itself, to revolve round him. It is forms us, that he began to entertain these notions at the year 1507; but not being satisfied with stating the year 1507; but not being satisfied with stating the year attreets he became definous general nature. but not being satisfied with stating to general nature of his hypothesis, he became desirous general nature the several periodical revolutions of the sets, and

thence of confirmating tables of their motions whic's might be more agreeable to truth than those of Ptolemy and Alphonfus. The observations he was enabled to make, however, must have been extremely inaccurate; as he tells us, that if with the infiruments he mad. use of he should be able to come within ten minutes of the truth, he should rejoice no less than Pythagoras did when he discovered the proportion of the hypothenule to the other two fides of a right-angled triangle. His work was completed in the year 1530; but he could not be prevailed upon to publish it till towards the end of his life, partly through diffidence, and partly through fear of the offence which might be taken at the fingularity of the doctrines fet forth in it. At last, overcome by the importunities of his friends, he fullered it to be published at their expence, and under the inspection of Schoner and Ossander, with a ded .cation to Pope Paul III. and a preface, in which it was attempted to palliate as much as possible the extraordinary innovations it contained. During the time of its publication, the author himself was attacked by a bloody flux, fucceeded by a palfy; fo that he received a copy only a few hours before his death, which

happened on the 23d of May 1543.

After the death of Copernicus, the aftronomical feience was greatly improved by Schoner, Nonius, Appian, and Gemma Frifius. Schoner furvived Copernicus only four years: however, he greatly improved the methods of making celeftial observations, reformed and explained the kalendar, and published a treatife of cosmography. Nonius had applied himself very early to the fludy of altronomy and navigation; but finding the inflruments at that time in use excessively maccurate, he applied himself to the invention of others which should be less liable to inconvenence. Thus he invented the astronomical quadrant, in which he divided the degrees into minutes by a number of concentric The first of these was divided into 90 equal parts, the fecond into 89, the third into 88, and to on as low as 46; and thus, as the index of the quadrant would always fall upon one or other of the divihons, or very near it, the minutes might be known by computation. He published many treatises on mathematical subjects, particularly one which detected the errors of Orontius, who had imagined that he could fquare the circle, double the cube, &c. by finding two mean proportionals betwixt two right lines. Appian's chief work was entitled The Cafarean Afternumy: and was published at Ingoldstadt in 1540, dedicated to the emperor Charles V. and his brother Ferdinand. In this he showed how to resolve astronomical problems by means of instruments, without either calculations or tables; to observe the places of the stars and planets by the aftrolabe: and to foretel ecliples, and describe the figures of them: the whole illustrated by proper diagrams. In his fecond book he describes the method of dividing an astronomical quadrant, and of using it properly. His treatife concludes with the observation of five comets. Gemma Frisins wrote a commentary on a work of Appian, entitled his Cofingraphy, with many observations of ecliples. He invented also the astronomical ring, and feveral other inflruments, which, though they could not boult of much exactness superior to others. were yet of confiderable utility in taking observations

at fea; and he is also memorable for being the first who proposed a time-keeper for determining the longirude at sea. George Joachim Rhéticus was a scholar of Copernicus, to attend whose lectures he gave up his professorship of mathematics at Wittemberg. For the improvement of astronomical calculations, he began to construct a table of sines, tangents, and secants, for every minute and ten seconds of the quadrant. In this work he first showed the use of secants in trigonometry, and greatly enlarged the use of tangents, first invented by Regiomontanus; but he assigned for the radius a much larger number of places than had been done before, for the greater exactness of calculation. This great work he did not live to accomplifh; but it was completed by his disciple Valentine Otho, and published at Heidelberg in 1594.

Several illustrious persons apply to the ftudy of

During this century, the lift of astronomers was dignified by fome very illustrious names. About the year 1561, William IV. landgrave of Hesse Cassel, applied himself to the study of astronomy. With the afaftronomy, fiftance of Rothman and Burgius, the former an aftronomer, the latter an excellent mathematical instrument maker, he erected an observatory on the top of his palace at Cassel, and furnished it with such instruments as were then in use, made in the best manner the artists of that age could execute. With these he made a great number of observations, which were by Hevelius preferred to those of Tycho Brahe, and which were published by Snellius in 1618. From these observationshe determined the longitudes and latitudes of 400 flars, which he inferted in a catalogue where their places are rectified to the beginning of the year

Dbfcrvaions of l'ycho Brahe.

is obfer-

ratory.

1593.

Tycho Brahe began his observations about the same time with the landgrave of Hesse, already mentioned. He observed the great conjunction of Saturn and Jupiter in 1563; and finding the inftraments he could procure very inaccurate, he made a quadrant capable of showing single minutes, and likewise a fextant four cubits radius. In 1571, he discovered a new star in the chair of Cassiopeia; which induced him, like Hip-This conparchus, to make a catalogue of the stars. tained the places of 777 stars, rectified to the year 1660; but instead of the moon, which was used by the ancients to connect the places of the fun and stars, Tycho fubflituted Venus as having little or no parallax, and yet being like the moon visible both day and night. By the recommendation of the landgrave of Hesse, he obtained from the king of Denmark the island of Huenna, opposite to Copenhagen, here an observatory Account of was built. The first stone of this building, afterwards Jraniburg, called Uraniburg, was laid in the year 1576. It was of a square form, one side of it being about 60 feet in length; and on the call and well fides were two round towers of 32 feet diameter each. The instruments more large and folid than had ever been feen be-four any aftronomer. They confifted of quadrants, fextants, circles, femicircles, armillæ both equatorial and zodiacal, parallactic rulers, rings, attrolabes, globes, clocks, and fun-dials. These instruments were so divided as to show single minutes; and in some the arch might he read off to 10 seconds. Most of the divisions were diagonal; but he had one quadrant divided achave amounted to 200,000 crowns. The method of dividing by diagonals, which Tycho greatly admired, was the invention of Mr Richard Chanceler, an Engliftman: Tycho, however, shows that it is not accurately true when straight lines are employed, and the circles at equal distances from each other; but that it may be corrected by making circular diagonals, which if continued would pass through the centie.

Tycho employed his time at Uraniburg to the best advantage; but falling into diferedit on the death of the king, he was obliged to remove to Holitein, and at lail found means to get himfelf introduced to the emperor, with whom he continued to his death. He is well known to have been the inventor of a fystem of aftronomy, which bears his name; and which he vainly endeavoured to establish on the ruins of that of Copernicus; but the simplicity and evident confonancy to the phenomena of nature, displayed in all parts of the Copernican fyllem, foon got the better of the unnatural and complicated lystem of Tycho. His works, however, which are very numerous, discover him to have been a man of vall abilities. After his death the castle of Uraniburg quickly fell to decay, and indeed feems to have been purposely pulled down; for, in 1652, when Mr Huct went to Sweden, it was almost level with the ground, and few traces of the walls could be discerned. None of the neighbouring inhabitants had ever heard of the name of Tycho or Uraniburg, excepting one old man, whom Mr Huet found out with great difficulty, and who had been a fervant in the family. All the discoveries of Purbach, Regiomontanus, and Tycho, were collected and published in the year 1621, by Longomontanus, who had been Tycho's favourite scholar.

While Tycho refided at Prague with the emperor, Discoveries he invited thither John Kepler, afterwards fo famous of Keplerfor his discoveries. Under the tuition of so great are. aftronomer, the latter quickly made an amazing progress. He found that his predecessors had erred in supposing the orbits of the planets to be circular, and their motions uniform: on the contrary, he perceived from his own observations, that they were elliptical, and their motions unequal, having the fun in one of the foci of their orbits; but that, however they varied in absolute velocity, a line drawn from the centre of the fun to the planet, and revolving with it, would always describe equal areas in equal times. He discovered, in the year 1618, that the squares of the periodical times are as the cubes of the distances of the planets; two laws which have been of the greatest istportance to the advancement of altronomy. He cems to have had some notion of the extensive power of the principle of gravity: for he tells us, that savity is a mutual power betwixt two bodies; that de moon and earth tend towards each other, and ould meet in a point nearer the earth than the moo in the proportion of the superior magnitude of the street, were they not hindered by their projectile, stions. He adds also, that the tides arise from the gravitation of the waters towards the moon: how afterwards substituted others ly to these principles, anetary motions.

as the causes of the Kepler were Mr Edward Wright, Cotemporary of Merchiston. To the former we and Napier bery good meridional observations of the

fun's altitude, made with a quadrant of fix feet radius, in the years 1594, 1595, and 1596; from which he greatly improved the theory of the fun's motion, and computed more exact tables of his declination than had been done by any person before. He published also, in 1599, an excellent Treatise, entitled, " Certain Errors in Navigation discovered and detected." To the latter we are indebted for the knowledge of logarithms; a discovery, as was justly observed by Dr Halley, one of the most useful ever made in the art of numbering. John Bayer, a German, who lived about the fame time, will ever be memorable for his work entitled Uranometria, which is a very complete celestial atlas, or a collection of all the confellations visible in Europe. To this he added a nomenclature, in which the flars in each conficliation are marked with the letters of the Greek alphabet; and thus every flar in the heavens may be referred to with the utmost precision and exactness. About the same time also, astronomy was cultivated by many other persons; abroad, by Maginus, Mercator, Maurolycus, Homelius, Schultet, Stevin, &c.; and by Thomas and Leonard Digges, John Dee, and Robert Flood, in England: but none of them made any confiderable improvement.

Invention and confequent difroveries.

The beginning of the 17th century was distinguishofficielespeced not only by the discovery of logarithms, but by that of telescopes; a fort of instruments by which afronomy was brought to a degree of perfection utterly inconceivable by those who knew nothing of them. The question concerning the inventor is discussed under the article Optics; but whoever was entitled to this merit, it is certain that Galileo was the first who brought them to fuch perfection as to make any confiderable discoveries in the celestial regions. With infirements of his own making, Galileo discovered the inequalities in the moon's furface, the fatellites of Jupiter, and the ring of Saturn; though this last was unknown to him after he had feen it, and the view he got made him conclude that the planet had a threefold body, or that it was of an oblong shape like an olive. He discovered spots on the sun, by means of which he found out the revolution of that luminary on his axis; and he discovered also that the milky way and nebulawere full of small stars. It was not, however, till fome time after these discoveries were made, that Galileo and others thought of applying the observations on Jupiter's fatellites to the purpose of finding the longitude of places on the furface of the earth; and even after this was thought of, astronomers found it so difhult to construct tables of their motions, that it was not 'ill after many observations had been made in dulant places of the world, that Cassini was able to determine was politions of the fatellites were most proper for finds of out the longitude. At last he perceived that the utrance of the first fatellite into the shadow of Jupiter, and the exit of it from the same, were the most prope for this purpose; that next to these the conjunctions of the satellites with Jupiter, or with one another, may be ade use of, especially when any two of them, moving in ontrary directions, meet with each other; and lastly, at observations on the shadows of the fatellites, which is observations on the thadows of the latellites, which no be feen on the disk of Jupiter, are useful, as also the last which are feen upon his face, and are carried along it is the oreater very upon his face, and are carried along it he greater velocity than has hitherto been discovered any of the other heavenly bodies.

While astronomers were thus busy in making new discoveries, the mathematicians in different countries Logarithwere no less earnestly employed in constructing loga-nuc tables with risk tables. The facilities of the state rithmic tables to facilitate their calculations. Benjamin Urfinus, an excellent mathematician of Brandenburgh, calculated much larger tables of logarithms than had been done by their noble inventor, and published them in 1625. They were improved by Henry Briggs, Savilian professor at Oxford; who by making unity the logarithm of ten, thus rendered them much more convenient for the purpoles of calculation. Logarithmic tables of fines and tangents were also composed by Mr Briggs and Adrian Vlacq at Goude, fo that the bufiness of calculation was now rendered nearly as easy as

In 1633, Mr Horrox, a young altronomer of very Transit of extraordinary talents, discovered that Venus would pass Venus first over the disk of the sun on the 24th of November Mr Hor-This event he announced only to one friend, rot. a Mr Crabtree; and these two were the only persons in the world who observed this transit the first time it had ever been viewed by human eyes. Mr Horrox made many uteful observations at the time; and had even formed a new theory of the moon, fo ingenious as to attract the notice of Sir Isaac Newton: but the hopes of altronomers from the abilities of this excellent young man were blafted by his death in the begin-

ning of January 1640.

About the year 1638 many learned men began to Found on affemble at Paris in order to hold conferences on dil- of the teaferent scientific subjects, which was the first foundation demy of toof the Royal Academy of Sciences in that capital, ences at Par This practice was introduced in France by Merfeinus, Routice and foon after at London by Oldenburg; which laid ciety at the foundation of the Royal Society there. About Lurder this time also the celebrated astronomer Hevelius slourished at Dantzic, building an observatory in his own house, and furnishing it with excellent instruments of his own construction; particularly octants and sextants of brass, of three and four feet radius, as well as telescopes, with which he constantly observed the spots and phases of the moon, and from which observations he afterwards compiled his excellent and beautiful work entitled Sclenographia. This noble building, together with all the books and inftruments it contained, was confumed by fire on the 26th of September 1679; but the memory, as well as the form and construction of the instruments, is preserved in a curious work of the ingenious inventor, entitled Machina Caleflis; tho' almost the whole impression of this book was involved in the same fate with the instruments it describes. The damage fustained on this occasion was estimated at 30,000 crowns.

The celebrated English mechanic Dr Hooke, who was cotemporary with Hevelius, had in the mean time. invented instruments with telescopic fights, which he preferred to those used by Hevelius so much, that a dispute commenced, which procured Hevelius a visit from Dr Halley. The latter had at that time taken a voyage to St Helena at the defire of the Royal Society, in order to observe and form a catalogue of the ftars in the fouthern hemisphere. The result of his observations with Hevelius's instruments was, that three feveral observations on the Spica Virginis and Regulus differed only a few seconds from each other. They were the invention of Tycho Brahe, and are-

peared in the years 1723, 1736, 1743, and 1757. He made new and most accurate tables of the motions of Jupiter's fatellites, from his own observations and those of Dr Pound; and from a multitude of observations of the fun, moon, and stars, was enabled to give the most accurate table of mean refractions yet extant, as well as the b ft methods of computing the variations of those refractions arising from the different states of the air as indicated by the thermometer and barometer. In 1750, having procured a very large transit instrument made by Mi Bud, and a new mural quadrant of brafs eight feet radius, he began to make observations with redoubled industry; fo that betwixt this time and his death, which happened in 1762, he made observations for setthing the places of all the stars in the British catalogue, together with near 1500 places of the moon, much the great r part of which he compared with the tables of M. Mayer.

35
iproveints by
if Tranch
ranoirs.

In the mean time the French astronomers were assiduous in their endeavours to promote the science of aftronomy. The theory of the moon, which had been given in a general way by Sir Isaac Newton, began to be particularly confidered by Messis Clairault, D'Alembert, Euler, Mayer, Simpson, and Walmsly; though Clairault, Euler, and Mayer, diffinguished themselves beyond any of the reft, and Mr Euler has been particularly happy in the arrangement of his tables for the eafe and expedition of computation. He was excelled in exactness, however, by Mayer, who published his tables in the Gottingen Acts for 1753. In these the errors in longitude never exceeded two minutes; and having yet farther improved them, he fent a copy to the lords of the British admiralty in 1755; and it was this copy which Di Bradley compared with his observations, as already mentioned. His last corrections of them were afterwards fent over by his widow; for which she and her children received a reward of 3000l. Accurate tables for Jupiter's fatellites were also composed by Mr Waigentin a most excellent Swedish astronomer, and published in the Upfal Acts in 1741; which have fince been corrected by the author in fuch a manner as to render them greatly superior to any ever published before.

36 ' M. de Caule.

Amongst the many French astronomers who contributed to the advancement of the science, we are particularly indebted to M. de la Caille, for a most excellent fet of folar tables, in which he has made allowances for the attractions of Jupiter, Venus, and the Moon. In 1750 he went to the Cape of Good Hope, in order to make observations in concert with the most celchrated astronomers in Europe, for determining the parallux of the moon, as well as of the planet Mars, and from thence that of the fun; from whence it appeared that the parallax of the fun could not greatly exceed 10 feconds. Here he re-examined and adjusted the places of the fouthern stars with great accuracy, and meafured a degree of the meridian at that place. In Italy the science was cultivated with the greatest assiduity by Signior Bianchini, Father Boscovich, Frisi, Manfredi, Zanotti, and many others; in Sweden by Wargentin already mentioned, Blingenstern, Mullet, and Planman; and in Germany, by Euler, elder and younger, Mayer, Lambert, Grischow, &c. In the year 1760 all the learned focieties in Europe began to prepare for

observing the transit of Venus over the sun, foretold by Dr Halley upwards of 80 years before it happened, showing at the same time the important use which might be made of it. Unfortunately, however, for tie cause of science, many of the altronomers sent out to observe this phenomenon were prevented by unavoidable accidents from reaching the places of their destination, and others were disappointed by the badness of the weather. It happened also, that the circumstances of the phenomenon were much less favourable for the purpose of determining the sun's parallax than had been expected by Dr Halley, owing to the faults of the tables he made use of; fo that, not withstanding all the labours of astronomers at that time, they were not able to determine the matter; and even after their observations in 1769, when the circumstances of the transit were more favourable, the parallax of the fun remained still uncertain.

Dr Bradley was succeeded in his office of astronomer royal by Mr Bliss, Savilian professor of astronomy at Oxford; who being in a very declining state of health at the time of his accession to the office, did not enjoy it long. He was succeeded by the learned Nevil Maskelyne, D. D. the present astronomer royal, whose name will be rendered immortal by his assiduity and success in bringing the lunar method of determining the longitude at sea into general practice.

Such was the general flate of aftronomy, when Mr Herschel's great discovery of augmenting the power of telescopes, beyond the most fanguine hopes of astronomers, opened at once a scene altogether unlooked for. By this indefatigable observer we are made acquainted with a new primary planet attended by two fecondarice belonging to our folar system; for that the latter now appears to have double the bounds formenly affigued to it; this new planet being at least twice the di-flance of Saturn from the fun. In the still farther diflant celeftial regions, among the fixed flars, his observations are equally surprising; of which we shall only say with Dr Priestley*, "Mr Herschel's late disco * Experient veries in and beyond the bounds of the folar fythem, and o the great views that he has given of the assungement Val. VI. of the stars, their revolutions, and those of the im-Pref. mense systems into which they are formed, are peculiarly calculated to inspire an ardent defire of seeing so great a scene a little more unfolded. Such discoveries as these give us a higher idea of the value of our being, by raifing our ideas of the fystem of which we are a part; and with this an earnest wish for the continuance of it."

SECT. I. Of the apparent Motions, Magnitudes, and Changes, in the celeftial Bodies, as feen by the naked eye.

As the true motions of bodies at a great distance are to be gathered only from a careful observation of their apparent ones, it is absolutely necessary for those who want to become acquainted with the true motions of the heavenly bodies, to know perfectly the different changes which take place in the heavens as seen from this earth, the only place from which any observation can be made. By carefully attending to these, a little knowledge of optics will enable us to understand with

N O S R M Y.

Motion,

Apparent motion of the fun.

38 Of the

moon.

Apparent great certainty not only the true fystem of nature, but also what appearance the heavens would make to a spectator placed in any part of the visible creation.

The first and most obvious phenomenon is the daily rifing of the fun in the east, and his fetting in the west: after which the moon and flars appear, fill keeping the fame wetterly course, till we lose fight of them altogether. This cannot be long taken notice of, before we must likewise perceive that neither the sun nor moon always rifes exactly in the same point of the heavens. If we begin to observe the sun, for instance, in the beginning of March, we will find that he feems to rife almost every day fensibly more to the northward than he did the day before, to continue longer above the horizon, and to be more vertical at mid day. This continues till towards the end of June, when he is obferved to move backward in the same manner; and this retrograde motion continues to the end of December, or near it, when he begins again to move forwards, and

The motion of the moon through the heavens, as well as her appearance at different times, is still more remarkable that those of the fun. When she first becomes visible at the time she is called the new moon, she appears in the western part of the heavens, and feems to be at no great distance from the sun himself. .Every night she not only increases in size, but removes to a greater distance from the sun; till at last she appears in the eastern past of the horizon, just at the time the fun disappears in the western. After this she gradually moves farther and farther eastward, and therefore rifes every night later and later, till at last she feems to approach the fun as nearly in the east as she did in the well, and rifes only a little before him in the morning, us in the first part of her course she set in the well not long after him. All these different appearance completed in the space of a month; after which they begin in the same order as before. They are not, however, at all times regular; for at some seathis of the year, particularly in harvest, the moon appears for feveral days to be flationary in the heavens, and to recede no farther from the fun, in consequence

of which the rifes for that time nearly at the same hour

Of the ftars.

every night. In contemplating the stars, it is observed that some of them have the fingular property of neither rifing in the east nor fetting in the west; but seem to turn round one immoveable point, near which is placed a fingle flar called the pole or pole flar. This point is more or less elevated according to the different parts of the earth from which we take our view. The inhabitants of Lapland, for instance, see it much more elevated above the horizon, or more vertical, than we do; we see it more vertical than it appears to the inhabitants of France and Spain; and they again, fee it more elevated than the inhabitants of Barbary. By continually travelling fouth, this star would at length feem depressed in the horizon, and another point would appear directly opposite to it, round which the stars in the fouthern part of the horizon would feem to turn. In this part of the heavens, however, there is no star so near the pole as there is in the northern part; neither is the number of stars in the fouthern part of the heavens fo great as in the northern. Supposing us still to travel fouthward, the north pole would then entirely disappear, and the whole hemisphere would appear to Appare turn round a fingle point in the fouth, as the northern Motion hemisphere appears to us to turn round the pole star. -The general appearance of the heavens, therefore, is that of a valt concave sphere, turning round two points fixed in the north and fouth parts of it, once in

When we farther confider the flars, we will find the Fixed that greatest part of them to keep their places with respect and planes to one another; that is, if we observe two stars having a certain apparent distance from each other this night, they will feem to have the fame to morrow, and every other fucceeding night; but we will ky no means obferve them to have the fame places either with respect to the fun or moon, as must be easily understood from what we have already faid. Neither do all the stars in the heavens appear to be of this fixed kind: Some of them, on the contrary, change their places very remarkably with regard to the fixed ftars, and with regard to one another. Of these, five were only observed formerly; but Mr Herschel has now discovered a fixth. They are distinguished by the appellation of planets, (from maave, to err or wander); and called by the names of Mercury, Venus, Mars, Jupiter, Saturn, and the Georgium Sidus. The fixed flars are likewise distinguished from the planets by their continually exhibiting that appearance which is called the fcintillation or twinkling of the flars. This is faid to arife from the exceeding minuteness of their apparent diameter; fo that the interpolition of any little substance, of which there are many floating in the atmosphere, continually deprives us of the fight of them; but the interpoling body foon changing its place, we again fee the star, and thus the twinkling is produced.

Mercury is a small star, but emits a very bright white light: though, by reason of his always keeping near the fun, he is feldom to be feen; and when he does make his appearance, his motion towards the fun is fo fwift, that he can only be different for a fhort time. He appears a little after funfet, and again a little before funrise.

Venus, the most beautiful star in the heavens, known by the names of the morning and evening flar, likewife keeps near the fun, though the recedes from him almost double the distance of Mercury. She is never feen in the eastern quarter of the heavens when the fun is in the western; but always seems to attend him in the evening, or to give notice of his approach in the

Mars is of a red fiery colour, and always gives a much duller light than Venus, though fometimes he equals her in fize. He is not subject to the same limitation in his motions as Mercury or Venus; but appears sometimes very near the sun, and sometimes at a great distance from him; sometimes rising when the fun fets, or fetting when he rifes. Of this planet it is remarkable, that when he approaches any of the fixed flars, which all the planets frequently do, these stars change their colour, grow dim, and often become totally invitible, though at some little distance from the body of the planet: but Mr Herschel thinks this has been exaggerated by former altronomers.

Jupiter and Saturn likewife often appear at great distances from the fun. The former shines with a bright white light, and the latter with a pale faint one; and

3 H 2

Motion,

pparent the motion of Saturn among the fixed stars is so slow, Motion, that, unless carefully observed, he will not be thought to move at all.

Besides the motions which we observe in all these Apparent 'planets, their apparent magnitudes are very different magnitudes at different times. Every person must have observed of the pla- that Venus, though the conflantly appears with great nets differ- fplendour, is not always equally big; and this apparent man and dufdifference of magnitude is fo remarkable, that the apferent pears no less than 32 times larger at some seasons than limes. at others. This increase of magnitude is likewise very remarkable in Mars and Jupiter, but less so in Saturn and Mercury.

Their irrezular moion.

Though we have thus described the motions of the planets, with respect to their apparent distances from the fun, they by no means appear to us to move regularly in the heavens, but, on the contrary, in the most complex and confused manner that can be imagined, fometimes going forward, fometimes backward, and foractimes feening to be flationary. They all feem to describe looped curves; but it is not known when any of these curves would return into themselves, except that of Venus, which returns into itself every eighth year. On each fide of the loops they appear flationary; in that part of each loop near the earth, retrograde; and in every other part of their path, di-

43 Comets.

Thefe, however, are not the only moving bodies which are to be observed in the celestial regions. The fix above mentioned are indeed the only ones which appear almost constantly, or disappear only at certain intervals, and then as certainly return. But there are others which appear at uncertain intervals, and with a very different aspect from the planets. These are very numerous, and no fewer than 450 are supposed to belong to our folar fystem. They are called Comets, from their having a long tail, fomewhat refembling the appearance of hair. This, however, is not always the case; for some comets have appeared which were as well defined and as round as planets: but in general they have a luminous matter diffused around them, or projecting out from them, which to appearance very much refembles the Aurora Borealis. When thefe appear, they come in a direct line towards the fun, as if they were going to fall into his body; and after having disappeared for some time in consequence of their proximity to that luminary, they fly off again on the other fide as fail as they came, projecting a tail much greater and brighter in their recess from him than when they advanced towards him; but, getting daily at a farther distance from us in the heavens, they continually lose of their splendour, and at last totally difappear. Their apparent magnitude is very different; fornetimes they appear only of the bigness of the fixed Rars; at other times they will equal the diameter of Venus, and fometimes even of the fun or moon. So, in 1652, Hevelius observed a comet which seemed not inferior to the moon in fize, though it had got so bright a splendour, but appeared with a pale and dim light, and had a difmal aspect. These bodies will also sometimes lose their splendour suddenly, while their apparent bulk remains unaltered. With respect to their apparent a otions, they have all the inequalifies of the planets; fometimes feeming to go forwards, fometimes backwards and fometimes to be flation- Apparent

Though the fixed flars are the only marks by which altronomers are enabled to judge of the courses of the moveable ones, and though they have never been ob-Fixed flors ferved to change their places; yet they feem not to be feemingly endued with the permanency even of the carth and deftrustible planets, but to be perishable or destructible by accident, and geneand likewise generable by some natural cause. Several rable. ftars observed by the ancients are now no more to be feen, but are deflroyed; and new ones have appeared, which were unknown to the ancients. Some of them have also disappeared for some time, and again become visible.

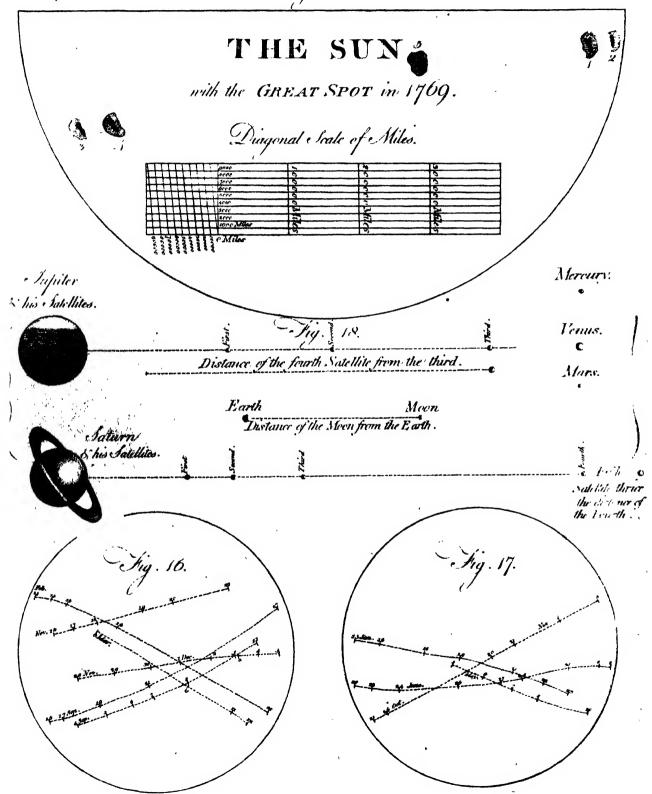

We are also assured from the observations of astronomers, that fome flars have been observed which never were feen before, and for a certain time they have diflinguished themselves by their superlative lustre; but afterwards decreafing, they vanished by degrees, and were no more to be feen. One of these stars being first feen and observed by Hipparchus, the chief of the ancient astronomers, set him upon composing a catalogue of the fixed flars, that by it posferity might learn whether any of the stars purish, and others are produced afresh.

After several ages, another new flar appeared to Tycho Brahe and the aftronomers who were cotemporary with him; which put him on the same design with Hipparchus, namely, the making a catalogue of the fixed flars. Of this, and other flars which have appeared fince that time, we have the following history by Dr Halley: "The first new flar in the thair of Dr Hal-Cassiopeia, was not seen by Cornelius Gemma on the key's hi-8th of November 1572, who fays, he that pight connew flars fidered that part of the heaven in a very ferene fky, and faw it not: but that the next night, November o. it appeared with a splendour surpassing all the fixed stars, and scarce less bright than Venus. This was not feen by Tycho Brahe before the 1 rth of the fame months but from thence he affures us that it gradually decreated and died away, so as in March 1574, after fixteen months, to be no longer visible; and at this day no figns of it remain. The place thereof in the sphere of fixed stars, by the accurate observations of the same Tycho, was o' 9° 17' a 1 200 4 op 15, with 53° 43' north: latitude.

"Such another star was seen and observed by the scholars of Kepler, to begin to appear on Sept. 30. A. vet. anno 1604, which was not to be feen the day before: but it broke out at once with a luftre surpassing that of Jupiter; and like the former, it died away gradually, and in much about the same time disappeared totally, there remaining no footsteps thereof in January 160%. This was near the ecliptic, following the right leg of Serpentarius; and by the observations of Kepler and others, was in 75 200 00' a 1ms * m, with north latitude 1º 56'. These two seem to be of a distinct species from the rest, and nothing like them has appeared fince.

"But between them, viz. in the year 1596, we have the first account of the wonderful star in Collo Ceti, feen by David Fabricius on the third of August, fl. vet. as bright as a star of the 3d magnitude, which has been fince found to appear and disappear periodically,

Fig. 15.

Apparent its period being precifely enough feven revolutions in fix Motion, years, though it returns notalways with the same lustre. Nor is it ever totally extinguished, but may at all times be seen with a fix feet tube. This was singular in its kind, till that in Collo Cygni was discovered. It precedes the first star of Aries 1° 40', with 15° 57' fouth latitude.

> " Another new flar was first discovered by William Jausonius in the year 1600, in pellore, or rather in eduttione, Colli Cygni, which exceeded not the third magnitude. This having continued some years, became at length fo finall, as to be thought by fome to have disappeared entirely: but in the years 1557, 1658, and 1659, it again arole to the third magnitude; tho' foon after it decayed by degrees to the fifth or firth magnitude, and at this day is to be feen as fuch in of 180 48' a 1m2 * m, with 55° 29' north latitude.

> A " fifth new flar was first seen by Hevelius in the year 1670, on July 15. fl. vet. as a flar of the third magnitude, but by the beginning of October was scarce to be perceived by the naked eye. In April following it was again as bright as before, or rather greater than of the third magnitude, yet wholly disappeared about the middle of August. The next year, in March 1672, it was feen again, but not exceeding the fixth magnitude: fince when, it has been no further visible, though

> we have frequently fought for its return; its place is 9' 3° 17' a 1 ma " my, and has lat. north 47° 28".

> "The firth and last is that discovered by Mr G. Kirch in the year 1686, and its period determined to be of 404 days; and though it rarely exceeds the fifth magnitude, yet it is very regular in its returns, as we found in the year 1714. Since then we have watched, as the ablence of the moon and clearnels of the weather would permit, to catch the first beginning of its appearance In a fix feet tube, that, bearing a very great aperture, thousen very minute stars. And on June 15. last, it was first perceived like one of the very least telescopical flars: but in the rest of that month and July, it gradually increased, so as to become in August visible to the naked eye; and to continued all the month of September. After that, it again died away by degrees: and on the 8th of December, at night, was scarce discernible by the tube; and as near as can be guesfed, equal to what it was at its first appearance on June 25th: so that this year it has been seen in all near six months, which is but little less than half its period; and the middle, and confequently the greatest brightnels, falls about the 10th of September.

fixed ftars.

Concerning the changes that happen among the Mr Monta- Concerning the changes that mathematics at nere's ac- fixed stars, Mr Montanere, professor of mathematics at Bononia, gave the following account, in a letter to the changes a- Royal Society, dated April 30th 1670. "There are now wanting in the heavens two ftars of the fecond magnitude in the stern of the ship Argo, and its vard; Dayerus marked them with the letters & and y. I and others observed them in the year 1664, upon the occasion of the comet that appeared that year: when they disappeared first, I know not: only I am fure that in the year 1668, upon the 10th of April, there was not the least glimpse of them to be seen; and yet the rest about them, even of the third and fourth magnitudes, remained the same. I have observed many more changes among the fixed flars, even to the number of

a hundred, though none of them are to great as those Appare I have showed.

The late improvements in astronomy, and particularly those in the construction of telescopes, have now given astronomers an opportunity of observing the changes which take place among the stars with much greater accuracy than could be formerly done. In a Mr Pipot paper in the 76th volume of the Philosophical Trans-remarks o actions, Mr Edward Pigot gives a differtation on the the acflars suspected by the altronomers of last century to be countered changeable. For the greater accuracy in the investi-variable. gation of this subject, he divides them into two classes, stars. one containing those which are undoubtedly changeable, and the other those which are only suspected to be fo. The former contains a lift of 12 stars, from the first to the fourth magnitudes; including the new one which appeared in Caffiopeia in 1572, and that in Serpentarius in 1604: the other contains the names of 38 flars of all magnitudes, from the first to the seventh. He is of opinion, that the celebrated new star in Cassiopeia is a periodical one, and that it returns once in 150 years. Mr Keill is of the same opinion: and Mr Pigot thinks, that its not being observed at the expiration of each period is no argument against the truth of that opinion; " fince (fays he), perhaps, as with most of the variables, it may at different periods have different degrees of luftre, fo as fometimes only to increase to the ninth magnitude; and if this should be the case, its period is probably much shorter." For this reason, in September 1782, he took a plan of the fmall flars near the place where it formerly appeared, but in four years had observed no alteration.

The star in the neck of the Whale had also been ex-Star in Co amined by Mr Pigot from the end of 1782 to 1786, lo Cetibut he never found it exceed the fixth magnitude; though Mr Goodricke had observed it on the 9th of August to be of the second magnitude, and on the 3d of September the same year it was of the third magnitude. Mr Pigot deduced its period from its apparant equality with a small star in the neighbourhood, and thence found it to be 320, 328, and 337 days,

The most remarkable of these changeable stars is Algol. that called Algol, in the head of Medufa. It had long been known to be variable; but its period was first afcertained by Mr Goodricke of York, who began to observe it in the beginning of 1783. It changes continually from the first to the fourth magnitude; and the time taken up from its greatest diminution to its least is found, at a mean, to be 2 days 20 hours 40 minutes and 3 feconds. During four hours it gradually diminishes in luftre, which it recovers during the fucceeding four hours; and in the remaining part of the period it invariably preserves its greatest fullre, and after the expiration of the term its diminution again commences. According to Mr Pigot, the degree of brightness of this star when at its minimum is variable in different periods, and he is of the same opinion with regard to its brightness when at its full; but whether thefe differences return regularly or not, has not been determintd.

The 420th of Mayer's catalogue, in Leo, has lately been shown to be variable by Mr Koch. Some years before 1782, that gentleman perceived it undoubtedly smaller than the 419th of the same catalogue. In Fe-

bruary.

parent bruary that year, it was of the same brightness with stion, the 410th, that is, of the seventh magnitude. Iu April 1783, it was of the ninith magnitude; and in the same month 1784, it was of the tenth. Mr Pigot could never observe this star, though he frequently looked for it with a night glass, and on the fifth of April 1785 with a three-feet achromatic transit influ-

hisble in Hy-

In 1704, Maraldi observed a variable star in Hydra, whose period he settled at about two years, though with confiderable variations: but from the observations even of Maraldi, Mr Pigot concludes, that its period was then only 494 days; and from fome others made by himfelf, he thinks that now it is only 487 days; fo that fince the time of Maraldi it has shortened seven days. The particulars relating to this star are as follow: 1. When at its full brightness it is of the fourth magnitude, and does not perceptibly change for a fortnight. 2. It is about fix months in increasing from the tenth magnitude and returning to the same: fo that it may be confidered as invisible during that time. 3. It is confiderably more quick, perhaps one half more fo, in its increase than in its decrease. 4. Though when at its full it may always be flyled a flar of the fourth magnitude, it does not constantly attain the fame degree of brightness, but the differences are very imall. This flar is the 30th of Hydra in Hevelius's catalogue, and is marked by him of the fixth magnitude.

The new star in Serpentarius, observed by Kepler, feems to have been of the same nature with that of Caffiopeia; and Mr Pigot therefore looks upon it also to be a periodical one, though, after taking a plan of the neared flars in that part of the heavens, in the year 1782, he could, in four years time, perceive no alteration.

The variation of the star & Lyræ was discovered by Mr Goodricke above mentioned, who suspects its period to be fix days nine hours; which coincides with the opinion of Mr Pigot.

The new star near the Swan's Head, observed by Don Anthelme in December 1669, foon became of the third magnitude, and disappeared in 1672. Mr Pigot has conflantly looked for it fince November 1781, but without success. He is of opinion, that had it only increafed to the 10th or 11th magnitude, he would have feen it, having taken a plan of all the neighbouring fmall flace.

The next variable flar in Mr Pigot's catalogue is the a Antinoi, whose variation and period he discoveted in 1785. From his corrected observations, he concludes that it continues at its greatest brightness 40 hours without decreasing; it is 66 hours after it begins to decrease before it comes to its full diminution; after which it continues stationary for 30 hours more, and then increases for 36 hours. In every period it frems to acquire its full brightness, and to be equally decreased.

The variable star in the Swan's Neck was observed for three years. The period of this star had been fettled by Maraldi and Cassini at 405, and by M. le Gental at 405.3 days; but from a mean of the obfer tions of Mr Pigot, it appears to be only 392. which several intervals of 15 years ought to be taken; and I am much inclined to believe that it will Apparent be found only 396 days as hours." The particulars Motion, relating to this flar are: 1. When at its full brightness it undergoes no perceptible change for a fortnight. 2. It is about three months and a half in increasing from the 11th magnitude to its full brightness, and the same in decreasing; for which reason it may be confidered as invisible during fix months. 3. It does not always attain the fame degree of luftre, being fometimes of the fifth and fometimes of the seventh magnitude.

In 1600, G. Jansonius discovered a variable star in Swan's the breakt of the Swan, which was afterwards observed B.east. by different astronomers, and supposed to have a period of about 10 years. The results of Mr Pigot's calculations from the observations of former astronomers are, I. That it continues in full luftre for five years. 2. It decreases rapidly for two years. 3. It is invisible to the naked eye for four years. 4. It increases slowly during seven years. 5. All these changes are completed in 18 years. 6. It was at its minimum at the end of the year 1663. 7. It does not always increase to the same degree of brightness, being sometimes of the third, and at others only of the fixth, magnitude. " I am entirely ignorant (lays Mr Pigot) whether it is fubject to the same changes in this century, having not met with any feries of observations on it; but if the above conjectures are right, it will be at its minimum in a very few years. Since November 1781 I have constantly seen it of the fixth magnitude. Sometimes I have suspected that it has decreased within these two last years, though in a very small degree."

The last star in Mr Pigot's first class is the Caphei, whose variation was discovered by Mr Goodricke. Its changes are very difficult to be feen, unless it is observed at the times of its greatest and least brightness. The refult of the observations hitherto made upon it are that its period confifts of 5 days 8 hours 37' on a meas. The following observations relate to some that of the

fecond class.

1. Hevelius's 6th Cassiopein was milling in 1782, nor Stars, vacould Mr Pigot find it in 1783 and 1784. riation of 2. E or 46th Andromedæ, faid to be variable, but the which is

evidence is not convincing to Mr Pigot.

3. Flamstead's 50,52, 7 Andromedæ, and Hevelius's 41 Andromedæ. The polition and characters of these stars differ considerably in different catalogues, and some of them are said, by Cassini, to have disappeared and reappeared. Mr Pigot therefore gives their comparative brightness as observed in the years 1783, 1784, and 1785, during which time he does not mention any particular change.

4. Tycho's 20th Ceti. " This (lays Mr Pigot) must be the star which Hevelius faid had disappeared, being Tycho's fecond in the Whale's Belly. There can hardly be any doubt that it is the z, misplaced by Tycho. This z is of the fourth or fifth magnitude."

5. 0, or the 17th Eridani of Ptolemy and Ulug Beigh. Flamstead says he could not see this star in 1691 and 1692: but in 1782, 1783, and 1784, Mr Pigot obferved in that place one of the feventh magnitude, which appeared always of the fame luftre.

6. Flamstead's 41 Tauri was supposed by Cassini to be either a new or variable flar; but Mr Pigot thinks there is no reason to be of that opinion. "That it is

wan's leck.

lead.

Apparent not new (fays he) is evident, fince it is Ulug Beigh's Motion, 26th and Tycho's 43d.

7. A star about 21 north of 53 Eridani, and 47 Eridani. Cassini supposed the first of these stars to be a new one, and that it was not visible in 1664. He mentions another star thereabouts, which he also

esteemed a new onc.

8. 2 Canis Majoris. Maraldi could not fee this ftar in 1670; but in 1692 and 1693 it appeared of the fourth magnitude. Mr Pigot made frequent observations upon it from 1782 to 1786, but could perceive no variation.

9. a, & Germinorum. " If any of these stars (fays our author) have changed in brightness; it is probably the s. In 1783, 1784, and 1785, the s was undoubt-

edly brighter than a.'

10. E Leonis. According to Montanari, this star was hardly visible in 1693. In 1783, 1784, and 1785, it was of the fifth magnitude. By Tycho, Flamstead, Mayer, Bradley, &c. it is marked of the fourth.

11. 4 Leonis. This flar is faid to have disappeared before the year 1667; but according to Mr Pigot's observations, was constantly of the fifth or fixth magnitude fince 1783.

12. 25th Leonis. In 1783, our author first perceived that this flar was missing, and could not perceive it in 1784 and 1785, even with a transit instrument.

13. Bayer's i Leonis, or Tycho's 16 Leonis, was not visible in 1709, nor could it be feen in 1785. It is a different flar from the i Leonis of the other cata-Togues, though Tycho's description of its place is the

fame. This star is suspected to change in brightness, on account of its being marked by Tycho, the prince of Helle, &c. of the second marked it of the third. In 1786, and for three years before, it appeared as a bright star of the fourth mag-

Is. Wirginis. This is supposed to be variable, because Flamitead, on the 27th of January 1680, could not fee it; but he observed it in 1677, and some years afterwards. Mr Pigot observed it frequently in 1784 and 1785, and found it a ftar of the fixth magnitude without any perceptible change.

16. Bayer's ftar of the fixth magnitude 1° fouth of g Virginis. "This star (fays Mr Pigot) is not in any of the nine catalogues that I have. Maraldi looked for it in vain; and in May 1785 I could not see the least appearance of it." It certainly was not of the

eighth magnitude.

17. A star in the northern thigh of Virgo, marked by Ricciolus of the fixth magnitude, could not be feen by Maraldi in 1709; nor was it of the ninth magnitude, if at all vitible in 1785.

18. The 91 and 92 Virginis. In 1785, one of these stars, probably the QI, was missing: the remain-

ing one is of the fixth or feventh magnitude.

19. a Draconis. Mr Pigot coincides in opinion with Mr Herschel, that this star is variable. Bradley, Flamflead, &c. mark it of the fecond magnitude, but in 1786 it was only a bright fourth. It was frequently examined by Mr Pigot from the 4th of October 1782, but without any alteration being perceived.

20. Bayer's star in the west scale of Libra. Maral. Appardi could not see this star, and it was likewise invisible Motte to Mr Pigot in 1784 and 1785.

21. No 6. of Prolemy and Ulug Beigh's unformed in Libra. This star is not mentioned in any other catalogues than the above. Mr Pigot frequently observed a little star of the seventh magnitude very near its

22. z Libræ. This star is thought to be variable, but Mr Pigot is not of that opinion, though " certainly (fays he) it is rather fingular, that Hevelius, whose attention was directed to that part of the heavens to find Tycho's 11th, did not find the x; and the more fo, as he has noticed two much smaller stars not far from it. During these three years I have found the x constantly of the fifth magnitude."

23. Tycho's 11th Libræ. Mr Pigot is of opinion that no fuch flar as this ever existed; and that it is no other than the * with an error of 2 degrees of longi-

tude.

24. 33 Serpentia. This star was missing in 1784: nor could it be perceived with a night-glass in 1785.

25. A flar marked by Bayer near & Urfæ Majoris. This flar could not be feen by Cassini; nor was Mr Pigot able to discover it with a night glass in 1782.

26. The e, or Prolemy and Ulug Beigh's 14th Ophiuchi, or Flamstead's 36th. Mr Pigot has no doubt that this is the star which is faid to have disappeared before the year 1695; and it is evident that it was not feen by Hevelius. In 1784 and 1785 Mr Pigot found it of the fourth or fifth magnitude; but he is far from being certain of its having undergone any change, especially as it has a fouthern declination of 26 degrees; for which reason great attention muit be paid to the state of the atmosphere.

27. Ptolemy's 13th and 18th Ophiuchi, fourth magnitude. Mr Pigot is of opinion that these stars are misplaced in the catalogues. The 18th of Ptolemy he thinks ought to be marked with a north latitude fuffead of a fouth, which would make it agree nearly with Flamstead's 58th; and he is also of opinion that the 13th of Ptolemy is the 40th of Flamilead.

28. 6 Sagittarii. Mr Heischel, as well as Mr Pigot, is of opinion, that this star has probably changed its magnitude, though the reason seems only to be the great disagreement concerning it among the different catalogues of stars.

29. & Serpentis. This star, according to Mr Montenari, is of variable magnitude; but Mr Pigot never could perceive any alteration.

30. Tycho's 27th Capricorni was miffing in Hevclius's time, and Mr Pigot could not find it with a tranfit instrument.

31. Tycho's 22d Andromedæ, and . Andromedæ. Mr Cashini informs us, that in his time the former had grown fo fmall that it could fearcely be feen, and Mr Pigot, that no star was to be seen in its place in 1784 and 1785: but he is of opinion that Cassini may have mistaken the . Andromedæ for the 22d; for which reason he observed this star three years, but without any alteration in its brightness.

32. Tycho's 19th Aquarii. Herelius fays that this flar was missing, and that Flamthead could not see it with his naked eye in 1679. Mr Pigot could not fee it in 1782; but is perfuaded that it is the same with

Flamilead's.

Flamstead's 56th marked f by Bayer, from which it is only a degree and a half dutant. The 53d of Flamstead, marked f in Ptolemy's catalogue, is a different ftar.

33. La Caille's 483d Aquarii was first discovered to be missing in 1778, and was not visible in 1783 and 1784.

Besides these there are several others certainly variable, but which cannot be feen in this country. There are some also suspected to be variable, but for which Mr Pigot thinks there is no reason. Mr Horschel also gives strong reasons for not laying great stress on all the observations by which new stars have been said to be discovered. Mr Pigot affires us from repeated experience, that even more than a fingle observation, if not particularized and compared with neighbouring flars, is very little to be depended upon; different fireaks of the clouds, the flate of the weather, &c, having often caused him err a whole magnitude in the

brightness of a star.

S4 Voltation's method of

As these changes to which the fixed stars are liable Recovering do not foem to be subject to any certain rule, Mr Wol-ratiation, laston has given an easy method of observing whether miong the they do take place in any part of the heavens or not, fixed flate, and that without much expence of inftruments or walter of time, which are great objections to aftronomical obfervations in general. His first idea was, that the work should be undertaken by astronomers in general; each taking a particular district of the heavens, and from time to time observing the right ascension and declination of every flar in that space allotted to him, framing an exact map of it, and communicating their observations to one common place of information. This method, however, being too laborious, he next proposes the noting down at the time, or making a drawing of what one fees while they are observing. A drawing of this kind once made, would remain, and could be confulted on any future occasion; and if done at first with care, a transient review would discover whether any fentible change had taken place fince it was last examined, which could not fo well be done by catalogues or verbal description. For this purpose he recommends the following method: " To a night-glass, but of Dolland's confiruction, which magnifies about fix times, and takes in about as many degrees of a great circle, I have added cross wires interlecting one another at an angle of 45 degrees. More wires may be crossed in other directions; but I apprehend these will be sufficient. This telescope I mount on a polar axis. One coarfely made, and without any divisions on its circle of declination, will answer the purpose, as there is no great occasion for accuracy in that respect ; but as the heavenly bodies are more readily, followed by an equatorial motion of the telefcope, fo their relative positions are much more easily discerned when they are looked at constantly as in the same direction. rizontal motion, except in the meridian, would be apt to millead the judgment. It is frarcely necessary to add, that the wires must stand so as for one to describe a parallel of the equator nearly; another will then be a horary circle, and the whole area will be divided into in the equal fectors.

Thus prepared, the telescope is to be pointed to a n star, which is to be brought into the centre or on intersection of all the wires. The relative po-

fitions of fuch other stars as appear within the field are Apparent to be judged of by the eye; whether at 1, 1, or 1 from Motion, the centre towards the circumference, or vice verfa; and fo with regard to the nearest wire respectively. Thefe, as one fees them, are to be noted down with a black lead pencil upon a large message card held in the hand, upon which a circle fimilarly divided is ready drawn. One of three inches diameter feems most convenient. The motion of the heavenly bodies in such a telescope is so slow, and the noting down of the stars so quickly done, that there is commonly full time for it without moving the telescope. When that is wanted, the principal flar is eafily brought back again into the centre of the field at pleasure, and the work refumed. After a little practice, it is altonishing how near one can come to the truth in this way: and tho' peither the right afterniou nor the declinations are laid down by it, nor the distances between the stars meafured; yet their apparent fituations being preferved in black and white, with the day and year, and hour, if thought necessary, written underneath, each card then becomes a register of the then appearance of the heavens; which is eafily re-examined at any time with little more than a transient view; and which will yet flow, on the first glance, if there should have happened in it any alteration of confequence."

Fig. 35. hows part of the Cozona Borealis delineated in this manner, and which was afterwards fully taken down by making the flare on B, 20 3, 15 5, 4, 1, 10, 10, 10, 10, 10 and r, sucqeffively central; and their were joined with some of the stars of Bootes, for the lake of connecting the whole, and united into one map, as represented fig. 36.

In observing in this way, it is evident, that the places of fuch flars as happen to be moder or very near any of the wires, are more to be depended aport than those which are in the intermediate spaces, especially if towards the edges of the fields; to allo those which are nearest to the centre, because better defined. and more within the reach of one wire or snother. For this reason, different stars of the same set must success fively be made contral; or brought towards one of the wires, where any laspicion arises of a millake, in order to approach neaser to a centainty thut if the fland of the telescope be tolerably well adjusted and fixed, this is foon dong.

In fuch a glass it is seldom that light sufficient for discerning the wires is wanting. When an illuminator is required, a piece of card or white pasteboard projecting on one fide beyond the tube, and which may be brought forward occasionally, is better than any other. By cutting acrofs a small segment of the object-glass, it throws a fufficient light down the tube though the candle be at a great distance, and one may lose fight of the falle glare by drawing back the head, and moving the eye a little to one fide, when the finall stars will be feen as if no illuminator was there. See a delineation of the principal fixed stars, with the apparent path of the fun among them, on Plate LXIV. and LXV.

A very remarkable appearance in the heavens is that Galaxy, of called the galaxy, or milky way. This is a broad circle, wilky way. fometimes double, but for the most part fingle, funrounding the whole celestial concave. It is of a whitish colour, somewhat resembling a faint aurora borealis; but Mr Brydone, in his journey to the top of Mount Altna, found that phenomenon to make a glorious ap-

leck.

Appearant pearance, being, as he expresses it, like a pure slame ces of Cele that fhot across the heavens.

Eclipics.

The only appearances, befides those already mentioned, which are very observable by the unassisted eye, are those unexpected obscurations of the sun and moon, commonly called eclipses. These are too well known, and attract the attention too much, to need any particular description. We have, however, accounts very well authenticated, of obscurations of the fun continuing for a much longer time than a common eclipfe poffibly can do, and likewife of the darkness being much greater than it usually is on such occasions: and that these accounts are probably true, we shall afterwards have occasion to observe.

SECT. II. Of the Appearances of the Celeflial Bodies as feen through Telefcopes.

1. THE fun, tho' to human eyes fo extremely bright and fplendid, is yet frequently observed, even through a telescope of but very small powers, to have dark spots on his furface. These were entirely unknown before the invention of telescopes, though they are sometimes of fufficient magnitude to be discerned by the naked eye, only looking through a smoked glass to prevent the brightness of the luminary from destroying the Bolar spots fight. The spots are said to have been first discovered when first in the year 1611; and the honour of the discovery is discovered, disputed betwixt Galileo and Scheiner, a German Jefuit at Ingoldstadt. But whatever merit Scheiner might have in the priority of the discovery, it is certain that Galileo far exceeded him in accuracy, though the work of Scheiner has confiderable merit, as containing obfervations selected from above 3000, made by himself. Since his time the subject has been carefully studied by all the astronomers in Europe; the refult of whose observations, as given by Dr Long, is to the following purpose.

Dr Long's account of them.

There is great variety in the magnitudes of the folar spots; the difference is chiefly in superficial extent of length and breadth; their depth or thickness is very small: some have been so large, as by computation to be capable of covering the continents of Asia and Africa; nay, the whole furface of the earth, or even five times its surface. The diameter of a spot, when near the middle of the disk, is measured by comparing the time it takes in passing over a cross hair in a telescope, with the time wherein the whole disk of the fun paffes over the fame hair; it may also be meafured by the micrometer; and by either of these methods we may judge how many times the diameter of the fpot is contained in the diameter of the fun. Spots are subject to increase and diminution of magnitude, and feldom continue long in the fame state. They are of various shapes; most of them having a deep black nucleus furrounded by a dufky closei, whereof the inner parts near the black are a little neighter than the outskirts. They change their shapes, fomething in the manner that our clouds do; though not often fo fuddealy: thus, what is of a certain figure to-day, thall to-morrow, or perhaps in a few hours be of a different one; what is now but one fpot, shall in a little time be broken into two or three; and fometimes two or three spots shall coalesce, and be united into one. Dr Long, many years fince, while he was viewing the image of the fun through a telescope call upon white paper, faw one roundish spot, by estimation Vor. II. Part II.

not much less than the diameter of our earth, break Appear digious velocity. This observation was singular at ital Botto the time; for though feveral writers had taken notice of this after it was done, none of them had been making any observation at the time it was actually doing.

The number of spots on the sun is very uncertain; fonetimes there are a great many, fometimes very few; and fometimes none at all. Scheiner made observations on the fun from 1611 to 1629; and f. ys he never found his disk quite free of spots, excepting a few days in December 1624. At other times he frequently faw 20, 30, and in the year 1625 he was able to count 50 spots on the fun at a time. In an interval atterwards of 20 years, from 1650 to 1670, scarce any spots were to be seen, and fince that time some years have furnished a great number of spots, and others none at all; but fince the beginning of the last century, not a year passed wherein some were not seen; and at present, says Mr Cassini, in his Elemens d'Astronomie published in 1740, they are so frequent, that the sun is feldom without fpots, and often thows a good number of them at a time.

From these phenomena, it is evident, that the fpots are not endowed with any permanency, nor are they at all regular in their shape, magnitude, number, or in the time of their appearance or continuance. Hevelius observed one that arose and vanished in 16 or 17 hours; nor has any been observed to continue longer than 70 days, which was the duration of one in the year 1676: those spots that are formed gradually, are gradually diffolved; while those that arise suddenly, are for the most part suddenly dissolved. When a spot disappears, that part where it was generally becomes brighter than the rest of the fun, and continues so for feveral days: on the other hand, those bright parts (called facula, as the others are called macula) sometimes turn to spots.

The folar spots appear to have a motion which The folar carries them across the sun's disk. Every spot, if it spots move continues long enough without being diffolved, appears from weft to enter the fun's disk on the east lide, to go from to cost. thence with the velocity continually increating till it has gone half its way; and then to move flower and flower, till it goes off at the west side; after which it disappears for about the same space of time that it spent in croffing the difk, and then enters upon the east fide again, nearly in the fame place, and croffes it, in the fame track, and with the fame unequal motion as before. This apparent inequality in the motion of the fpots is purely optical, and is in fuch proportion as demonstrates them to be carried round equably or in a circle, the plane of which continued passes through or near the eye of a spectator upon the earth.

Besides the real changes of the spots already mentioned, there is another which is purely optical, and is owing to their being feen on a globe differently turned towards us. If we imagine the globe of the fun to have a number of circles drawn upon its surface, all paffing through the poles, and cutting his equator at equal diffances, thefe circles which we may call meridians, if they were visible, would appear to us at unequal distances, as in fig. 2. Now, suppose a spot were round, and to large as to reach from one meri-(LVIII.o dian to another, it would appear round only at g, when LX. it was in the middle of that half of the globe which is to-

searan- wards our earth; for then we view the full extent of it of Cele-in length and breadth: in every other place it turns Bodies away from us, and appears narrower, though of the fame length, the farther it is from the middle; and on its coming on at a, and going off at n, it appears as fmall as a thread, the thin edge being then all that we

The motion of the spots is in the order of the signs (the same way that all motions in the solar system those of the comets alone excepted, are performed); and therefore, as the earth revolves round the fun the fame way with the folar spots, one of these will appear to remain longer on the disk than it would otherwise do if the earth remained at rest. Thus, in fig. 3. let ABCI) be the orbit of the earth, a b c d the equa-7111. or) tor of the fun; let a be a spot feen in the middle of the disk by a spectator upon the earth at A. The fpot being carried round through bc d, according to the order of the letters, will in about 25 days bring it again to a; but during that interval, the earth will be got to B, and the middle of the disk at b; fo that about two days more will intervene before a spectator upon the earth at C will view it in the middle of the the apparent disk at c. There are, however, but few inflances of fuch returning spots; so that Scheiner, out of his multitude of observations, found only three or four of this kind.

As fig. 2. is an orthographic projection of meridians on the fun's disk, it may be thought that they would show the apparent diurnal motion of the spots; fo that, for example, a fpot which to-day at noon is in the meridian marked a, would to-morrow at noon be in that marked b, the next day in that marked c, and fo on: but Scheiner fays, that, casting the sun's picture on paper through a telescope, the distance between the place of a spot at noon any given day and the place at noon the day immediately preceding, or the day immediately following, will be greater when the fpot is near the circumference of the disk than according to the orthographic projection it ought to be. This deviation of fpots he thought owing to the refraction of the glass in the telescope being greater near the circumference than in the middle; and he was confirmed in this opinion, by finding, that if spots were observed by letting the fun shine through a small hole without a glass, upon white paper held at a good distance from the hole in a dark room, their places would then be every day according to the orthographic projection. But he found this method of observing the solar spots artended with great difficulties. Another proof that this deviation of the folar spots is occasioned by the different refraction of the glasses of the telescope, is deduced from the following experiment. Our author pierced with a needle 12 fmall holes at equal distances in a thin plate of brass; and placing the plate before the glasses of a short telescope, let the sun shine through, receiving 12 bright spots upon a white paper placed in fuch a manner that the light might fall perpendicularly upon it. Here also he found the distances between the spots near the outside greater than between those in the middle; whereas when he received them upon paper without any glasses, the situation of the bright spots exactly corresponded to that of the small holes in the plate.

The face of the fun, when clear of spots, seen by

the naked eye through a fmoked or coloured glafs, or Appearanthrough a thin cloud, or the vapours near the houzon, ces of Cele-appears all over equally luminous: but when viewed flial Bodies. thro' the telefcope, the glaffes being fmoked or coloured, besides the difference between the faculæ and the other parts, the middle of the disk appears brighter than the outfkirts; because the light is darted more directly towards us from the middle than from any other part, and the faculæ appear more diffinctly near the fides, as being on a darker ground than in the

The phenomena of the folar spots, as delivered by Account of Scheiner and Hevelius, may be fummed up in the their phefollowing particulars: 1. Every fpot which hath a nomena by nucleus, or confiderably dark part, hath also an unbra, different or fainter shade, surrounding it. 2. The boundary betwixt the nucleus and umbra is always diffined and well defined. 3. The increase of a spot is gradual, the breadth of the nucleus and umbra delating at the same time. 4. In like manner, the decrease of a spot is gradual, the breadth of the nucleus and umbra contracting at the same time. 5. The exterior boundary of the umbra never confifts of sharp angles; but is always curvilinear, how irregular foever the outline of the nucleus may be. 6. The nucleus of a spot, whilst on the decrease, often changes its figure by the umbra encroaching irregularly upon it, infomuch that in a fmall space of time new encroachments are discernible, whereby the boundary betwixt the nucleus and umbra is perpetually varying. 7. It often happens, by these encroachments, that the nucleus of a spot is divided into two or more nuclei. 8. The nuclei of the spot vanish sooner than the umbra. 9. Small umbræ are often feen without nuclei. 10. An umbra of any considerable fize is seldom feen without a nucleus in the middle of it. 11. When a spot which consisted of a nucleus and umbra is about to disappear, if it is not succeeded by a facula, or spot brighter than the rest of the disk, the place where it was is foon after not diftinguishable from the rest.

In the Philosophical Transactions, Vol. LXIV. Dr Wilson, professor of astronomy at Glasgow, hath given a differtation on the nature of the folar spots, and mentions the following appearances: 1. When the spot is about to disappear on the western edge of the sun's limb, the eastern part of the umbra first contracts, then vanishes, the nucleus and western part of the umbra remaining; then the nucleus gradually contracts and vanishes while the western part of the umbra remains. At last this disappears also; and if the spot remains long enough to become again visible, the eastern part of the umbra first becomes visible, then the nucleus; and when the spot approaches the middle of the disk, the nucleus appears environed by the umbra on all fides, as already mentioned. 2. When two spots he very near to one another, the umbra is deficient on that fide which lies next the other fpot : and this will be the case, though a large fpot should be contiguous to one much smaller; the umbra of the large spot will be totally wanting on that fide next the small one. If there are little spots on each fide of the large one, the umbra does not totally vanish; but appears flattened or pressed in towards the nucleus on each fide. When the little spots disappear, the umbra of the large one extends itself as usual. This circumstance, he observes, may sometimesprevent the disappearance of the unibra in the manner

above-

Appearan- above mentioned; so that the western umbra may disces of Cele-appear before the nucleus, if a small spot happens to flial Bodies. break out on that fide.

In the same volume, p. 337. Mr Wollaston observes, that the appearances mentioned by Dr Wilson are not constant. He positively affirms, that the facult or bright spots on the sun are often converted into dark ones. "I have many times (fays he) observed, near the eastern limb, a bright facula just come on, which has the next day shown itself as a spot, though I do nor recollect to have feen fuch a facula near the western one after a spot's disappearance. Yet, I believe, both these circumstances have been observed by others; and perhaps not only near the limbs. The circumstance of the faculæ being converted into spots, I think I may be fure of. That there is generally (perhaps always) a mottled appearance over the face of the fun, when carefully attended to, I think I may be as certain It is most visible towards the limbs, but I have undoubtedly feen it in the centre; yet I do not recollect to have observed this appearance, or indeed any spots, towards his poles. Once I faw, with a twelve-inch reflector, a spot burst to pieces while I was looking at it. I could not expect fuch an event, and therefore cannot be certain of the exact particulars; but the appearance, as it struck me at the time, was like that of a piece of ice when dashed on a frozen pond, which breaks to pieces and flides in various directions." He also acquaints us, that the nuclei of the spots are not always in the middle of the umbræ; and gives the figure of one seen in November 13. 1773, which is a remarkable in-Mr Dunn's stance to the contrary. Mr Dunn, however, in his new Atlas of the Mundane System, gives some particulars very different from the above. "The face of the sun (fays he) has frequently many large black spots, of various forms and dimentions, which move from east to well, and round the fun, according to some observations in 25 days, according to others in 26, and according to some in 27 days. The black or central part of each spot is in the middle of a great number of very fmall ones, which permit the light to pass between them. The small spots are scarce ever in contact with

> The spots are by no means confined to one part of the fun's disk; though we have not heard of any being observed about his polar regions; and though their direction is from east to west, yet the paths they deferibe in their course over the disk are exceedingly different; fometimes being straight lines, fometimes curves, fometimes defeending from the northern to the fouthern part of the disk, sometimes ascending from the fouthern to the northern, &c. This was observed by Mr Derham (Philof. Tranf. No 330.), who hath given figures of the apparent paths of many different spots, wherein the months in which they appeared, and their particular progress each day, are marked.

the central ones: but what is most remarkable, when

the whole spot is near the limb of the sun, the fur-

rounding small ones form nearly a straight line, and

the central part projects a little over it, like Saturn in

Belides these spots, there are others which sometimes and Venus appear very round and black, travelling over the disk of the fun in a few hours. They are totally unlike the others, and will be shown to proceed from an interposition of the planets Mercury and Venus between the earth

and the fun. Excepting the two kinds of spots above- Appear mentioned, however, no kind of object is discoverable ces of Od on the furface of the fun, but he appears like an im-fual Bodie menfe ocean of elementary fire or light.

2. With the moon the case is very different. Many Telescopic darkish spots appear in her to the naked eye; and view of the through a telescope, their number is prodigiously in-moon. creafed: the also appears very plainly to be more protuberant in the middle than at the edges, or to have the figure of a globe, and not a flat circle. When the moon is horned or gibbous, the one fide appears very ragged and uneven, but the other always exactly defined and circular. The spots in the moon always keep their places exactly; never vanishing, or going from one fide to the other, as those of the fun do. We fometimes fee more or le of the northern and fouthern, and eaftern and western part of the disk or face; but this is owing to what is called her libration, and will hereafter be explained.

The aftronomers Florentius, Langrenus, John Hevelius of Dantzic, Grimaldus, Ricciolus, Callini, and M. de la Hire, have drawn the face of the moon as she is feen through telefcopes magnifying between 200 and 300 times. Particular care has been taken to note all the shining parts in her surface; and, for the better diffinguishing them, each has been marked with a proper name. Langrenus and Ricciolus have divided the lunar regions among the philosophers, astronomers, and other eminent men; but Hevelius and others, fearing lest the philosophers should quarrel about the division of their lands, have endeavoured to spoil them of their property, by giving the names belonging to different countries, islands, and fers on earth, to different parts of the moon's furface, without regard to fituation or figure. The names adopted by Ricciolus, however, are those which are generally followed, as the names of Hipparchus, Tycho, Copernicus, &c. are more pleating to astronomers than those of Africa, the Mediterranean fea, Sicily, and Mount Ætna. On Plate LXIII. is a tolerably exact representation of the full moon in her mean libration, with the numbers to the principal spots according to Ricciolus, Caffini, Mayer, &c. The allerisk refers to one of the volcanoes discovered by Dr Herschel, to be afterwards more particularly noticed. The names are as follow:

Grimaldus. Galilæus. Aristarchus. Keplerus. Gaffendus. Shicardus. Harpalus. Heraclides, 9 Lanshergius. Reinoldus. Copernicus. 11 Helicon. 13 Capuanus. 14 Bullialdus. 15 Eratofthenes. 16 Timocharis. 17 Plato. 18 Archimedes.

We have already observed, that when the planet Mars approaches any of the fixed stars, they lofe their light, and fometimes totally disappear before he feems to touch them: but it is not fo with the moon; for though the very often comes in betwixt us and the stars, they preferve their lustre till immediately in feeming contact with her, when they fuddenly disappear, and as fuddenly re-appear on the opposite side. When Saturn, however, was hid by the moon in June 1762, Mr Dunn, who watched his appearance at the emersion, observed a kind of faint shadow to follow him for a little from the edge of the moon's disk. This appearance is represented fig. 88.

3. Mercury, when looked at through telescopes spears almagnifying about 200 or 300 times, appears equally avs equal luminous throughout his whole furface, without the least dark spot. He appears indeed to have the same difference of phases with the moon, being sometimes horned, fometimes gibbous, and fometimes shining almost with a round face, though not entirely full, because his enlightened fide is never turned directly towards us; but at all times perfectly well defined with-

out any ragged edge, and perfectly bright.

4. Dr Long informs us, that the earliest account he had met with of any spots seen by means of the telescope on the disk of Venus was in a collection of letters printed at Paris in 1665, in one of which Mr Auzout relates his having received advice from Poland that Mr Burratini had, by means of large telescopes, feen spots upon the planet Venus similar to those upon the moon. In 1667, Cassini, in a letter to Mr Petit, mentions his having for a long time carefully obferved Venus through an excellent telescope made by Campani, in order to know whether that planet revolved on its axis or not, as he had before found Jupiter and Mars to do. But though he then observed fome spots upon her, he says, that even when the air was quiet and clear, they appeared faint, irregular, and not well defined; fo that it was difficult to have fuch a diffinct view of any of them as to be certain that it was the same spot which was seen again in any fubfequent observation; and this difficulty was increafed, in the first place, when Venus was in her inferior semicircle; because at that time she neal be viewed through the thick vapours near the horizon; though otherwise it was most proper, on account of her being then nearest to us. In the second place, if we would observe her at some height above those vapours, it could only be for a short time; and thirdly, when she is low in her inferior circle, and at that time nearest the earth, the enlightened part of her is too small to discover any motion in it. He was therefore of opinion, that he should succeed better in his observations when the planet was about its mean distance from us, showing about one half of her enlightened hemisphere; at which time also he could observe her for a much longer time above the gross atmospherical vapours. His first appearance of success was October 14. 1666, at three quarters past five in the evening; when he saw

a bright spot (fig. 37.), but could not then view that Appearanfpot long enough to draw any inference concerning the ces of Celeplanet's motion. He had no farther success till the flial Bodies. 20th of April the following year; when, about a quarter of an hour before funrife, he began again to LXVI. perceive on the disk of Venus, now about half enlightened, a bright part near the fection, distant from the fouthern horn a little more than a fourth part of the diameter of the disk, and near the eastern edge. He took notice also of a darkish obling spot nearer to the northern than the fouthern horn; at funrife the bright part was advanced faither from the fouthern horn than when he first observed it; but though he was pleafed to find that he had now a convincing proof Why the of the planet's motion, he was surprised that the spots spots seem moved from fouth to north in the lower part of the to move from fouth disk, and from north to fouth in the upper part; a to north, kind of motion of which we have no example except &c. in the librations of the moon. This, however, was occasioned by the situation of the planet's axis. Caffini expected to have found the rotation of Venus fimilar to that of Jupiter and Mars, both of which have their axis perpendicular to their respective orbits, and turn round according to the order of the figns; fo that in each of them the motion of the inferior half of their respective globe, or that part next the sun, is from east to west; in the superior half from west to cast: but in Venus, whose axis is inclined 75 degrees towards her orbit, the coincidence is fo near, that one half of her disk appears to move from fouth to north. the other from north to fouth.

On the 21st of April, at funrife, the bright part particular was a good way off the fection, and about a fourth acrount of part of the diameter distant from the fouthern horse, the appear-When the fun was eight degrees fix minutes high, ir ances of the feemed to be got beyond the centre, and was cut feent through by the fection. At the time the fun was fertimes. ven degrees high, the fection cut it in the middle, which showed its motion to have some inclination towards the centre.

May 9. a little before funrife, the bright fpot was feen near the centre, a little to the northward, with two obscure ones situated between the section and the circumference, at a distance from each other, equal to that of each of them from the nearest angular point or horn of the planet. The weather being at that time clear, he observed for an hour and half a quarter the motion of the bright spot, which seemed to be exactly from fouth to north, without any fenfible declination to east or west. A variation was at the same time perceived in the darkish spot too great to be ascribed to any optical cause. The bright spot was alfo seen on the 10th and 13th days of May before sunrife between the northern horn and the centre, and the fame irregular change of darkish spots was taken notice of; but as the planet removed to a greater distance from the earth, it became more difficult to observe these appearances. The above phenomena are reprefented as they occurred, in figs. 37-43.

But though, from the appearances just now related, Castini's M. Cassini was of opinion that Venus revolved on her conclusions. axis, he was by no means to positive in this matter as concerning with regard to Mars and Jupiter. "The spots on the revolu-these (says he) I could attentively observe for a whole hus on her night, when the planets were in opposition to the fun : axis.

Piate

I could

Appearan- I could fee them return to the same situation, and con-

ees of Cele- fider their motion during fome hours, and judge whethal Bodies ther they were the fame spots or not, and what time they took, in turning round: but it was not the same with the spots of Venus; for they can be observed only for fo short a time, that it is much more difficult to Difficulties know with certainty when they return into the same according fituation. I can, however, supposing that the bright the fe obser-spot which I observed on Venus, and particularly this year, was the same, say that she finishes her motion, whether of rotation or libration, in lefs than a-day; fo that, in 23 days nearly, the spot comes into the fame fituation on nearly the fame hour of the day, though not without some irregularity. Now (supposing the bright (pot observed to be always the faine) whether this motion is an entire turning round, or only

a libration, is what I dare not politively affirm."

In 1660 M. Cassim again observed Venus through a teletcope, but could not then perceive any spots upon

her furface; the reason of which Du Hamel conjec-

tures to have been the fluctuation of the vapours near

the horizon, which prevented them from being visible.

seen on her disk till the year 1726; when, on the 9th

of February, Bianchini, with some of Campani's tele-

scopes of 90 and 100 Roman palms, began to observe

the planet at the altitude of 40° above the horizon, and continued his observations till, by the motion of

feveral spots, he determined the position of her axis to

be inclined as above mentioned, that the north pole pointed at a circle of latitude drawn through the 20th degree of Aquarius, elevated 15° or 20° above the orbit

of Venue. He delineated also the figures of several spots

which he supposed to be seas, and complimented the king of Portugal and some other great men by calling them by their sames. Though none of Bianchina observations were continued long enough to

know whether the spots, at the end of the period af-

figured for the rotation of the planet, would have been

in a different fituation from what they were at the be-

ginning of it; yet, from observations of two and of four days, he concluded the motion of the spots to be

at the rate of 15° per day; at which advance the planet.

but without farther observation it could not be deter-

mined which of the two was the period of revolu-

tion; for if an observer should at a particular hour,

suppose seven in the evening, mark exactly the place

of a spot, and at the same hour next evening find

the fpot advanced 15°, he would not be able to de-

termine whether the spot had advanced only 15°, or

had gone once quite round with the addition of 15°

more in part of another rotation. Mr Bianchini,

however, supposes Venus to revolve in 24 days eight

hours; the principal proof adduced for which is an

observation of three spots, A B C, being situated as

in fig. 44. when they were viewed by himfelf and fe-

veral persons of distinction for about an hour, during

which they could not perceive any change of place.

The planet being then hid behind the Barbarini palace

they could not have another view of her till three

hours after, when the spots still appeared unmoved. 14 Now (fays Mr Bianchini) if her rotation were fo

Iwift as to go round in 23 hours, in this fecond view,

three hours after the former, the spots must have ad-

Branchini's However, we hear nothing more of any spots being chiervations.

Doubte concerning must turn round either once in 24 days or in 23 hours; the time the takes. up in revolving round her arie,

Plate

and there would have been no more but two spots, A and B, to have been feen." Cassini, the son, in a memoir for 1732, denies the Dispute beconclusion of Bianchini to be certain. He fays, that twixt Cassiduring the three hours interval, the spot C might be ni and gone off the disk, and the spot B got into the place Bianchini. thereof, where, being near the edge, it would appear less than in the middle. That A, succeeding into the place of B, would appear larger than it had done near the edge, and that another spot might come into the place of A; and there were other spots besides these three on the globe of the planet, as appears by the figures of Bianchini himfelf, particularly one which would naturally come in the place of A. That if the rotation of Venus be supposed to be in 23 hours, it will agree with Bianchini's observations, as well as with those of his farher; but that, on the other supposition, the latter mult be entirely rejected as erroncous: and he concludes with telling us, that Venus had frequently been observed in the most favourable times by Mr Maraldi and himfelf with excellent telefcopes of 80 and 100 feet focus, without their being able to fie any difunct spot upon her disk. " Perhaps (fays Dr Long) those feen by Bianchini had disappeared, or the air in France was not clear enough; which last might be the reason why his father could never see those spots in France which he had observed in Italy, even when he made use of the longest telescopes." Neither of these astronomers take notice of any indentings in the curve which divides the illuminated part from the dark in the disk of Venus, though in some views of that planet by Fontana and Ricciolus, the curve is indented; and it has from thence been concluded, that the furface of the planet is mountainous like that of the moon. This had also been supposed by Burratini, already mentioned; and a late writer has observed, that, " when the air is in a good flate for observation, mountains like those of the moon may be observed with a very powerful telefcope."

Cassini, besides the discovery of the spots on the disk Cassini disof Venus by which he was enabled to afcertain her re-covers her. volution on an axis, had also a view of her satellite or satellite moon, of which he gives the following account.-" A. D. 1686, Aug. 28. at 15 minutes after four in the morning, looking at Venus with a telescope of 34 feet, I saw, at the distance of one-third of her diameter eastward, a luminous appearance, of a shape not well defined, that feemed to have the same phase with Venus, which was then gibbous on the western side. The diameter of this phenomenon was nearly equal to a fourth part of the diameter of Venus. I observed it attentively for a quarter of an hour, and having left off looking at it for four or five minutes, I faw it no more; but daylight was then advanced. I had feen a like phenomenon which refembled the phase of Venus, . Jan. 25. A. D. 1672, from 52 minutes after fix in. the morning to two minutes after feven, when the brightness of the twilight made it disappear. Venuswas then horned; and this phenomenon, the diameter whereof was nearly a fourth part of the diameter of Venus, was of the fame shape. It was distant from . the fouthern horn of Venus, a diameter of the planetes

vanced near 50 degrees; fo that the spot C would have Appear been gone off at R, the spot B would have succeeded cen of Cell into the place of C, the spot A into the place of B, final Bodie

ppearun- on the western side. In these two observations, I was hal Bodies a confishence as not to be very well fitted to reflect the light of the fun; and which, in magnitude, bore nearly the same proportion to Venus as the moon does to the earth, being at the same distance from the sun and the earth as Venus was, the phases whereof it resembled. Notwithstanding all the pains I took in looking for it after these two observations, and at divers other times, in order to complete so considerable a discovery, I was never able to fee it. I therefore suspended my judgment of this phenomenon. If it should return often, there will be these two epochas, which, compared with other observations, may be of use to find out the periodical time of its return, if it can be reduced to any rule."

he transit

A fimilar observation was made by Mr Short on the also by Mr 22d of October 1740, about sunrise. He used at this time a reflecting telescope of about 16.5 inches, which magnified between 50 and 60 times, with which he perceived a small star at about 10' distance from Venus, as meafured by the micrometer; and, putting on a magnifying power of 240 times, he found the flar put on the fame appearance with the planet herfelf. Its diameter was somewhat less than a third of that of the primary, but its light was less vivid, though exceedingly sharp and well defined. The same appearance continued with a magnifying power of 140 times. A line, passing through the centre of Venus and it, made an angle of 18 or 20 degrees with the equator: he faw it several times that morning for about the space of an hour, after which he loft fight of it, and could never find it again.

> From this time the fatellite of Venus, though very frequently looked for by aftronomers, could never be perceived, which made it generally believed that Cassim and Mr Short had been mistaken; but as the tranfits of the planet over the fun in 1761 and 1769 feemed to promile a greater certainty of finding it, the fatellite was very carefully looked for by almost every one who had an opportunity of feeing the transit, but generally without fuccess. M. Baudouin at Paris had provided a telescope of 25 feet, in order to observe the passage of the planet over the sun, and to look for its fatellite; but he did not succeed either at that time or in the months of April and May following. Mr Montaigne, however, one of the members of the Society of Limoges, had better fuccels. On the 3d of May 1761, he perceived, about half an hour after nine at night, at the distance of 20' from Venus, a small crescent, with the horns pointing the fame way as those of the planet; the diameter of the former being about one-fouth of that of the latter; and a line drawn from Venus to the fatellite making an angle with the vertical of about 20° towards the fouth. But though he repeated this observation several times, some doubt remained whether it was not a small star. Next day he faw the same star at the same hour, distant from Venus

about half a minute, or a minute more than before, with making with the vertical an angle of 10° below showing e north fide; fo that the fatellite feemed to have at which the an arc of about 20°, where of Venus was the at which hed an arc of about 30°, whereof Venus was the longer to and the radius 20'. The two following nights His first azy, so that Venus could only be seen; but on at three que of May, at the same hour as before, he saw

the fatellite again above Venus, and on the north fide, Appearanat the distance of 25' or 26' upon a line which made an cos of Celeangle of about 45°, with the vertical towards the right flial Bodies hand. The light of the fatellite was always very weak, but it had the fame phasis with its primary, whether viewed together with it in the field of his telescope or by itself. The telescope was nine feet long, and magnified an object between 40 or 50 times, but had no micrometer: fo that the diffances above mentioned are only from estimation.

Fig. 4. represents the three observations of Mr Mon-(LVIII. or) taigne. V is the planet Venus; Z N the vertical LX. E C, a parallel to the ecliptic, making then an angle with the vertical of 45°; the numbers 3, 4, 7, mark the fituations of the fatellite on the respective days. From the figure it appears that the points 3 and 7 would have been diametrically opposite, had the fatellite gone 150 more round the point V at the last observation; so that in four days it went through 155°. Then, as 155° is to four days or 96 hours, so is 360 to a fourth number, which gives 9 days 7 hours for the whole length of the fynodical revolution. Hence M. Baudouin concluded, that the distance of this fatellite was about 60 of the semidiameters of Venus from its furface; that its orbit cut the ecliptic nearly at right angles; had its ascending node in 22° of Virgo; and was in its greatest northern digression on the 7th at nine at night; and he supposed that at the tranfit of the primary the fatellite would be feen accompanying it. By a subsequent observation, however, on the 11th of May, he corrected his calculation of the periodical time of the fatellite, which he now enlarged to 12 days; in confequence of which he found, that it would not pale over the disk of the line slow with its primary, but go at the difference of these des from his fouthern limb; though if the same of its remaind be 15 hours longer than 12 days; it might may the then pals over the fun after Venus was gunt off. I the state that it imagined the reason why this satellite was to difficult to difficult to be observed might be, that one part of its globe was to be feen crusted over with spots, or otherwise unlit to rested the light of the fun. By comparing the periodical time of this fatellite with that of our moon, he computed the quantity of matter in Venue to be nearly equal to that in our earth; in which case it must have consider-

This is all the evidence which has yet been published concerning the existence of the satellite of Venus; as it does not appear that, during the transit of 1769, any of the observers had the good fortune to perceive it. In the Philosophical Transactions for 1761, Mr Hirst gives an account of his having observed an atwere made at Fort St George; and looking attentions contively at that part of the fun's disk where he expected corning the the planet would enter, he plainly perceived a faint simosphere shade or penumbra; on which he called out to his two of Venus. affifiants, "'Tis a coming !" and two or three seconds after, the first external contact took place, in the moment whereof all the three agreed; but he could not fee the penumbra after the egress; and of the other two gentlemen, one had gone home, and the other loft the planet out of the field of his telescope. Mr Dunn at Chelsea saw a penumbra, or finall diminution of

able influence in changing the obliquity of the eclip-

tic, the latitudes and longitudes of stars, &c.

Appearan- light, that grew darker and darker for about five feces of Cele- conds before the internal contact preceding the egrefs, stial bodies from whence he determines that Venus is surrounded

with an atmosphere of about 50 geographical miles high. His observations he tells us, were made with an excellent fix-feet Newtonian reflector, with a magnifying power of 110, and of 220 times; he had a clear dark glass next his eye, and the sun's limb appeared well defined; but a very narrow waterish penumbra appeared round Venus. The darkett part of the planet's phasis was at the distance of about a fixth part of her diameter from its edge; from which an imperfect light increased to the centre, and illuminated round about.

In the northern parts of Europe this penumbra could not be feen. Mr Wargentin, who communicated several observations of the first external contact, fays, that he could not mark the time exactly, because of the undulation of the limb of the fun; but thought it very remarkable that, at the egress, the limb of Venus that was gone off the fun showed itself of a faint light during almost the whole time of emersion. Mr Bergman, who was then at the observatory at Upsal, begins his account at the time when three-fourths of the disk of the planet was entered upon that of the fun; and he fays, that the part which was not come upon the fun was visible, though dark, and furrounded Place LXI. by a crescent of faint light, as in fig. 7.: but this appearance was much more remarkable at the egrels; for as foon as eny part of the planet was got off the fun, that part was viable with a like crefcent, but brighter, ig. 8. As more of the planetary disk went off that farthelt from the fun grew fainter, and vanished until at last only the horns could be feen, as in fig. 9. The total ingress was not inflantaneous: but as two drops ... af water when about to part, form a ligament between them: to there was a dark swelling stretched out between Venus and the fun, as in fig. 10. ; and when this ligament broke, the planet appeared to have got about an eighth part of her diameter from the nearest limb of the fun, fig. 11.; he faw the like appearance at going off, but not fo distinct, fig. 12. Mr Chappe likewise took notice, that the part of Venus which was not upon the funwas visible during part of the time of ingress and egress; that it was farther surrounded by a small luminous ring of a deep yellow near the place that appeared in the form of a crefcent, which was much brighter at the going off than coming upon the fun; and that during the whole time the disk of Venus was upon the fun he faw nothing of it. The time of total ingress was inflantaneous like a flath of lightning; but at the egress the limb of the sun began to be obscured three seconds before the interior contact. Some of the French astronomers attributed this luminous ring round Venus to the inflection of the fun's rays, as they also do the light seen round the moon in folar eclipses; but Mr Chappe supposes it to have been owing to the fun enlightening more than one half of the planetary globe, though he owns this cause not to be altogether sufficient. Mr Fouchy, who observed the transit at I.a Muette in France, perceived, during the whole time, a kind of ring round Venus, brighter than the rest of the sun, which became fainter the farther it went from the planet, but appeared more vivid

in proportion as the fun was clearer. Mr Ferner, Appearant who observed at the same place, consirms the testimo-co of Cele ny of Mr Fouchy. "During the whole time (fays that Bodies! he) of my observing with the telescope, and the blue and green glasses, I perceived a light round about Venus, which followed her like a luminous atmosphere more or lefs lively, according as the air was more or less clear. Its extent altered in the same manner; nor was it well terminated, throwing out as it were, tome feeble rays on all fides."

"I am not clear (fays Dr Long) as to the mean-Dr Long's. ing of the luminous circle here mentioned; whether, opinion on when the whole planet was upon the fun, they faw a thefe obfice ring of light round it, distinct from the light of the vations. fun; or whether they mean only the light which furrounded that part of Venus that was not upon the fun." Mr Chappe takes this and other accounts of the observations made in France in this latter sense; and though he fometimes called the lumpious part of the crefeent that furrounded the part of the planet not upon the fun a ring, he explains himfelf that he did fo, because at the coming upon the fun he perceived it at one fide of the planet, and at the opposite fide on its going off: for which reason he supposed that it furrounded it on all fides. See fig. 13, 14.

5. Much larger and more remarkable spots have been \$pots when? perceived on the disk of Mars than that of any other first icen on; primary planet. They were first observed in 1666 by Mars. Caffini at Bologna with a telescope of Campani about 16 feet long; and continuing to observe them for a month, he found they came into the same situation in 24 hours and 40 minutes. The planet was observed by fome altronomers at Rome with longer telescopes made by Eustachio Divini; but they assigned to it a rotation in 13 hours only. This, however, was afterwards shown by Mr Cassini to have been a miftake, and to have arisen from their not distinguishing the opposite sides of the planet, which it seems have spots pretty much abke. He made further observations on the spots of this planet in 1070; from whence he drew an additional confirmation of the time the planet took to revolve. The fpots were again observed in fubsequent oppositions; particularly for several days in 1704 by Maroldi, who took notice that they were not always well defined, and that they not only changed their shape frequently in the space between two oppositions, but even in the space of a month. Some of them, however, continued of the fame form long enough to afcertain the time of the planet's revolution. Among these there appeared this year an oblong spot, resembling one of the belts of Jupiter when broken. It did not reach quite round the body of the planet; but had, not far from the middle of it, a finall protuberance towards the north, fo well defined that he was thereby enabled to fettle the period of its revolution at 24 hours 39 minutes; only one minute Plate less than what Cassimi had determined it to be. See LXVII.

fig. 45. The near approach of Mars to the carth in 1719, gave a much better opportunity of viewing him than had been obtained before; as he was then within 21 deg. of his perihelion, and at the fame time in opposis tion to the fun. His apparent magnitude and brightness were thus fo much increased, that he was by the vulgar taken for a new flar. His appearance at that.

appearantimes, as feen by Maraldi through a telescope of 34 s of Cele-feet long, is represented fig. 46. There was then a ial Bodies long belt that reached half way round, to the end of which another shorter belt was joined, forming an obtuse angle with the former, as in fig. 47. This angular point was observed on the 19th and 20th of Auguft, at 11 hours 15 minutes, a little east of the middle of the disk; and 37 days after, on the 25th and 26th of September, returned to the fame fituation. This interval, divided by 36, the number of revolutions contained in it, gives 24 hours 40 minutes for the period of one revolution; which was verified by another spot of a triangular shape, one angle whereof was towards the north pole, and the base towards the south, which on the 5th and 6th of August appeared as in fig. 48. and after 72 revolutions returned to the same situation on the 16th and 17th of October. The appearances of Mars, as delineated by Mr Hook, when viewed through a 36 feet telescope, are represented fig. 28. He appeared through this instrument as hig as the full moon. Some of the belts of this planet are faid to be parallel to his equator; but that feen by Maraldi was very much inclined to it.

Besides these dark spots, former astronomers took spots about notice that a segment of his globe about the south pole he poles of exceeded the rest of his disk so much in brightness, that it appeared beyond them as if it were the fegment of a large globe. Maraldi informs us, that this bright spot had been taken notice of for 60 years, and was more permanent than the other fpots on the planet. One part of it is brighter than the rest, and the least bright part is subject to great changes, and has some-

times disappeared.

A fimilar brightness about the north pole of Mars was also sometimes observed; and these observations are now confirmed by Mr Herschel, who hath viewed the planet with much better instruments, and much higher magnifying powers, than any other astronomer ever was in possession of. His observations were made with a view to determine the figure of the planet, the position of his axis, &c. A very particular account of them is given in the 74th volume of the Philosophical hefe spots. Transactions, but which our limits will not allow us to infert. Fig. 49-72. show the particular appearances of Mars, as viewed on the days there marked. The magnifying powers he used were sometimes as high as 932; and with this the fouth polar spot was found to be in diameter 41". Fig. 73 shows the connexion of the other figures marked 64, 65, 66, 67, 68, 69, 70, which complete the whole equatorial succession of spots on the disk of the planet. The centre of the circle marked 65 is placed on the circumference of the inner circle, by making its distance from the circle marked 67 answer to the interval of time between the two observations, properly calculated and reduced to sidereal measure. The same is done with regard to the circles marked 66, 67, &c.; and it will be found by placing any one of these connected circles in such a manner as to have its contents in a similar situation with the figures in the fingle reprefentation, which bears the same number, that there is a sufficient resemblance between them; though fome allowance must undoubtedly be made for the distortions occasioned by this kind of projection.

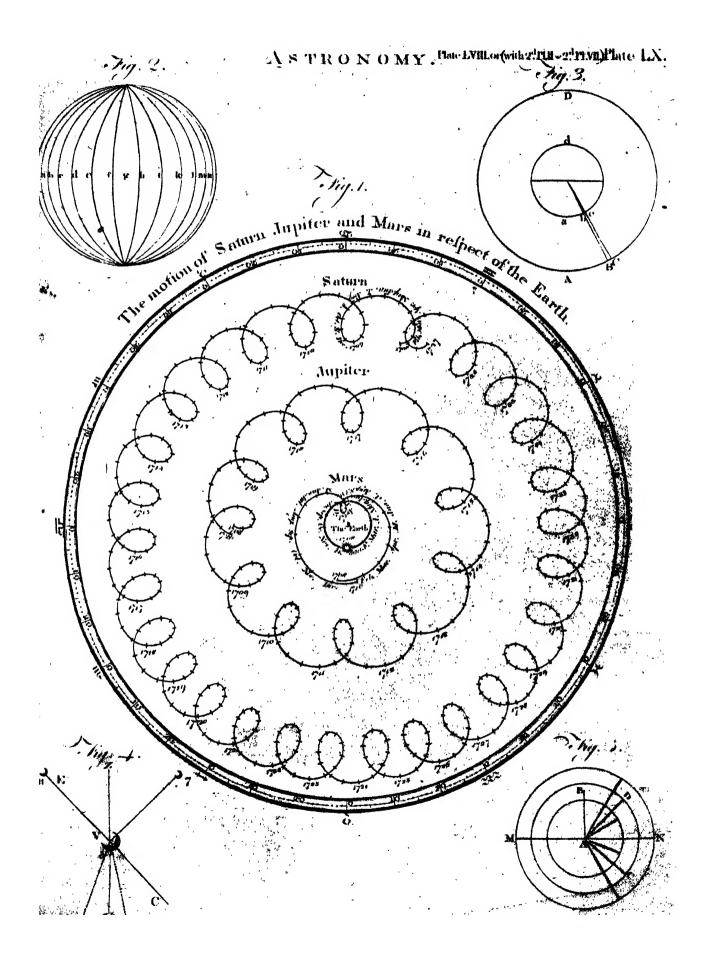

With regard to the bright spots themselves, Mr Her-

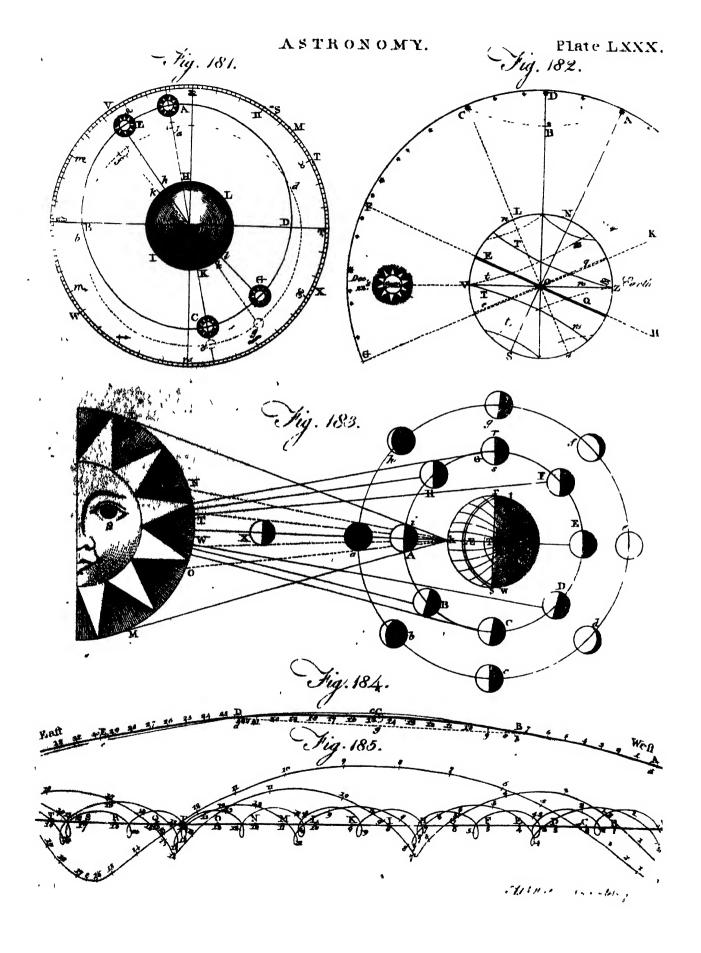

since fichel informs us, that the poles of the planet are Appearan-not exactly in the middle of them, though nearly so ces of Cele-" From the appearance and disappearance (says he) of that Bodies. the bright north polar spot in the year 1781, we collect that the circle of its motion was at some consider- Causes of able distance from the pole. By calculation, its lati-the appearatude must have been about 76 or 77° north; for I find ance and that, to the inhabitants of Mars, the declination of the disappearfun, June 25th, 12 hours 15 minutes of our time was ance of about 9° 56' fouth; and the spot must have been so their spots. far removed from the north pole as to fall a few degrees within the enlightened part of the disk to become visible to us. The fouth pole of Mars could not be many degrees from the centre of the large bright fouthern fpot of the year 1781; though this fpot was of such a magnitude as to cover all the polar regions father than the 70th or 65th degree; and in that part which was on the meridian, July 3d, at 10 hours

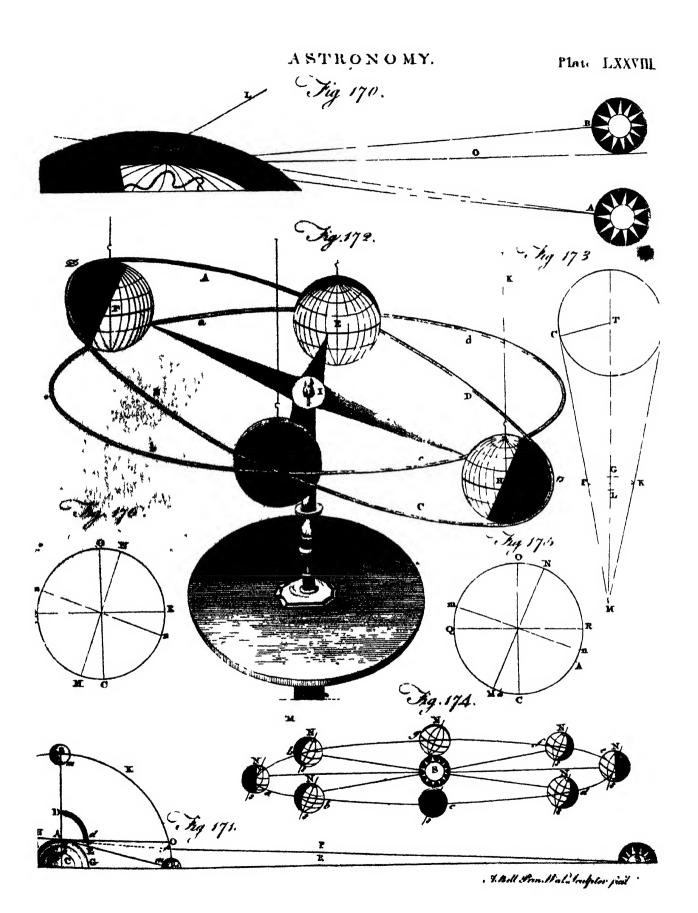

54 minutes, perhaps a little farther.

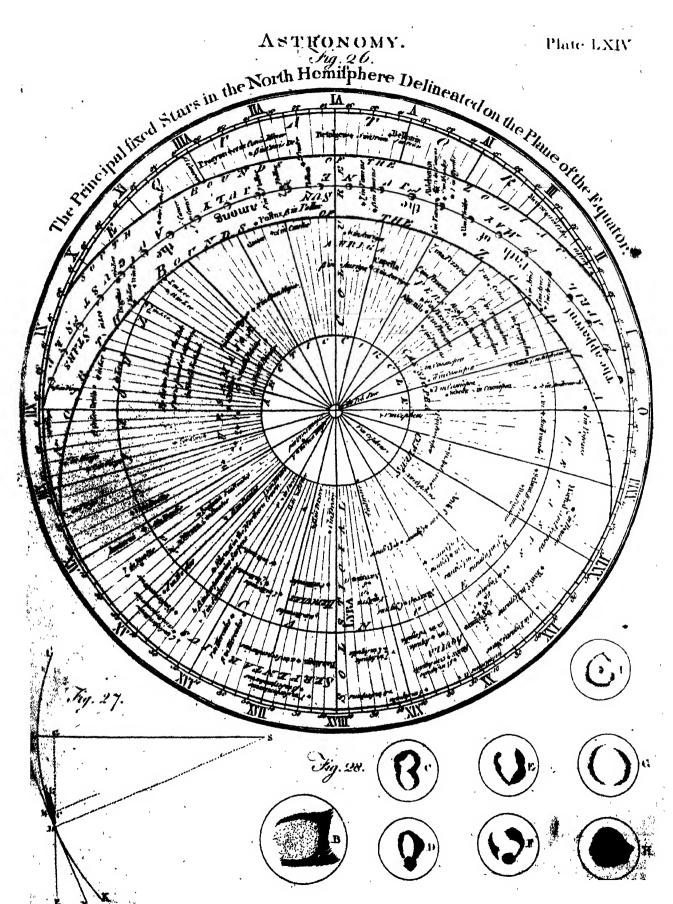

" From the appearances of the fouth polar spot in 1781, we may conclude that its centre was nearly polar. We find it continued visible all the time Mars revolved on his axis; and to present us generally with a pretty equal share of the luminous appearance, a fpot which covered from 45 to 60° of a great circle on the globe of the planet, could not have any confiderable polar distance. From the observations and calculations made concerning the poles of Mars, we of the exmay conclude, that his north pole must be directed to-act position wards fome point of the heavens, between 9 34 35' of the poles and o' 7° 15'; because the change of the firmation of of Mark the pole from left to right, which happened in the time the planet passed from one place to the other, is a plain indication of its having gone through the node of its axis. Next, we may allo conclude, then the node must be considerably nearer the latter point of the ecliptic than the former: for, whatever be the inclination of the axis, it will be feen under equal angles at equal distances from the node. But by a trigonometrical process of solving a few triangles, we soon discovered both the inclination of the axis, and the place where it interfects the ecliptic at rectangles (which, for want of a better term, I have perhaps improperly called its node.) Accordingly I find by calculation, that the node is in 17° 47' of Pifces, the north pole of Mars being directed towards that part of the heavens; and that the inclination of the axis to the ecliptic is 59° 40'. By further calculations we find that the pole of Mars on the 17th of April 1777, was then actually 81° 27' inclined to the ecliptic, and pointed towards the left as feen from the fun.

"The inclination and fituation of the node of the axis of Mars, with respect to the ecliptic, being found, may be thus reduced to the orbit of the planet himfelf. Let EC (fig. 74.) be a part of the ecliptic, Plate OM part of the orbit of Mars, PEO a line drawn LXVII, from P, the celestial pole of Mars, through E, that point which has been determined to be the place of the node of the axis of Mars in the ecliptic, and continued to O, where it intersects his orbit. Now, if, according to M. de la Lande, we put the node of the orbit of Mars for 1783 in 18 17° 58', we have from the place of the node of the axis, that is, 118 17° 47' to the place of the node of the orbit, an arch EN of 60° 11'. In the triangle NEO, right-angled

Appearan- at E, there is also given the angle E NO, according ces of the to the same author, 1° 51', which is the inclination of Boles thro, the orbit of Mars to the celiptic. Hence we find the Te'ef. opes, angle EON 89° 5', and the fide ON 60° 12'. Again, when Mars is in the node of its orbit N, we have by calculation the angle P N E=63° 7'; to which adding the angle E NO=1° 51', we have P NO=64° 58': from which two angles, P O N and P NO, with the distance O N, we obtain the inclination of the axis of Mars, and place of its node with respect to its own orbit; the inclination being 61° 18', and the place of the node of the axis 586 31' preceding the interfection of the ecliptic with the orbit of Mars, or in our 19° 25' of Pifces."

Of the fea-5 - 22 a 411 Mars.

Our author next proceeds to show how the seasons in this planet may be calculated, &c. Which conjectures, though they belong properly to the next fection, yet are so much connected with what has gone before, that we shall insert here what he says upon the

fubject.

" Being thus acquainted with what the inhabitants of Mars will call the obliquity of their ecliptic, and the fituation of their equinoctial and folfitial points, we are furnished with the means of calculating the scafons on that planet, and may account, in a manner which I think highly probable, for the remarkable appear-

ance about its polar regions.

" But first, it may not be improper to give an inflance how to refolve any query concerning the Martial feafons. Thus, let it be required to compute the declination of the sun on Mars, June 25. 1781, at midnight of our time. If m, &, ti, 23, &c. (fig. 75.) represent the ecliptic of Mars, and or so is by the ecliptic of our planet, A a b B the mutual interfection of the Martial and terrestrial coliptics, then there is given the heliocentric longitude of Mars, m = 9' 10" 30'; then taking away fix figns, and a b or m a = 1 17 58', there remains / m = 1 22° 32'. From this a ch, with the given inclination 10 51 of the orbits to each other, we have conne of inclination to radius, as tangent of b m to tangent of B M = 18 22° 33'. And taking away B m = 15 1° 20', which is the complement to 1 B (or 25 A, already shown to be 18 28° 31'), there will remain on M = 08 21° 4', the place of Murs in its own orbit; that is, on the time above mentioned, the fun's longitude on Mars will be 65 210 4'; and the obliquity of the Martial ecliptic, 28° 42', being also given, we find, by the usual method, the sun's declination 9° 56' fouth. " The analogy between Mars and the earth is per-

86 onfiderblance het ist the to th and Mars.

able refem- haps by far the greatest in the whole solar system. Their diurnal motion is nearly the same : the obliquity of their respective ecliptics not very different: of all the superior planets, the distance of Mars from the fun is by far the nearest alike to that of the earth; nor will the length of the Martial year appear very different from what we enjoy, when compared to the g, furprising duration of the years of Jupiter, Saturn, White spot and the Georgium Sidus. If then we find that the about the globe we inhabit has its polar regions frozen and copoles of Mars, fuppofed to be with mountains of ice and fnow that only partly melt when alternately exposed to the fun, I may occasioned well be permitted to surmise, that the same causes may probably have the same effect on the globe of Mars; that the bright polar spots are owing to the vivid re-

Vol. II. Part II.

flection of light from frozen regions; and that the re- Appear duction of those spots is to be ascribed to their being cos of the exposed to the sun. In the year 1781, the fouth po- Centuar lar foot was extremely large, which we might well 1 defenpes expect, as that pole had but lately been involved in a whole twelvemonth's darkness and absence of the fun; but in 1783, I found-it confiderably fmaller than before, and it decreased continually from the 20th of May till about the middle of September, when it feened to be at a stand. During this last period the footh pole had already been above eight months enjoying the benefit of fummer, and full continued to receive the fun-beams, though towards the latter end in fuch an oblique direction as to be but little benefited by then. On the other hand, in the year 1781, the north poler fpot, which had then been its twelvemonth in the funflune, and was but lately returning into darkness, appeared fmall, though undoubtedly increasing in fize. Its not being visible in the year 1783, is no objection to these phenomena, being owing to the position of

"That a planetary globe, fuch as Mais, turning on Of the an axis, flould be of a spheroidical form, will easily fird spheroidical admittance, when two familiar inflances in Jupiter and form of the earth, as well as the known laws of gravitation and Mers the centrifugal force of rotatory bodies. lead the way to the reception of fuch doctrines. So far from creating difficulties, or doubts, it will rather appear fingular, that the spheroidical form of this planet has not already been noticed by former astronomers; and yet reflecting on the general appearance of Mais, we foon find, that opportunities of making observations on its real form cannot be very frequent: for when it is near enough to view it to an advantage, we fee it generally gibbous, and its appositions are so scarce, and of so short a diration, that in more than two years time, we have not above three or four weeks for fuch observations. B.fides, aftronomers being generally accustomed to fee this planet distorted, the spheroidical form might easily

the axis, by which it was removed on, of light.

be overlooked.

" September 25. 1783. At 9h 50', the equatorial Difference diameter of Mars measured 21" 53"; the polar diame-betweet the ter 21" 15", full measure; that is certainly not too equatorial small. This difference of the diameters was shown, on and polar the 28th of the fame month, to Mr Wilson of Glasgow, counters, who saw it perfectly well, so as to be convinced that of Mars. it was not owing to any defect or diffortion occationed by the lens; and because I wished him to be fatisfied of the reality of the appearance, I reminded him of feveral precautions; fuch as cauting the planet to pafa directly through the centre of the field of view, and judging of its figure when it was most diffined and best defined, &c. Next day the difference between the two diameters was shown to Dr Blagden and Mr Aubert. The former not only faw it immediately, but thought the flattening almost as much as that of Jupiter. Mr Aubert also saw it very plainly, so as to entertain no manner of doubt about the appearance.

" September 30th, 10h 52', the equatorial diameter was 22" 9", with a magnifying power of 278. By a second measure it was 22" 31", full large; the polar diameter, very exact, was 21" 26". On the first of October, at 10h 50', the equatorial diameter mensured 103 by the micrometer, and the polar 98; the value of the divisions in feconds and thirds not being well

determined

ppearan-

When Jupiter is in quadrature with the fun, the earth tes of the is farthest out of the line that passes through the centres middlesthro of the fun and Jupiter, and therefore the shadow of Telescopes, the planet is then most exposed to our view: but even - then the body of the planet will hide from us one fide of that part of the shadow which is nearest to it, through which the first sitellite passes; which is the reason, that though we see the entrance of that satellite into the shadow, or its coming out from thence, as the earth is fituated on the east or west side thereof, we cannot see them both; whereas the other fatellites going through the thadow at a greater distance from Jupiter, their ingress and egress are both visible.

103 Telefcopic. spearance of Saturn.

IC4 His ring first discovered by Huygens.

7. Saturn, when viewed through a good telescope, makes a more remarkable appearance than any of the other planets. Galileo first discovered his uncommon shape, which he thought to be like two small globes, one on each fide of a large one : and he published his discovery in a Latin sentence; the meaning of which was, that he had feen him appear with three bodies; though, in order to keep the discovery a secret, the letters were transposed. Having viewed him for two years, he was surprised to see him become quite round without these appendages, and then after some time to assume them as before. These adjoining globes were what are now called the anse of his ring, the true shape of which was first discovered by Huygens about 40 years after Galileo, first with a telescope of 12 feet, and then with one of 23 feet, which magnified objects 100 times. From the discoveries made by him and other astronomers, it appears that this planet is surrounded by a broad thin ring, the edge of which reflects little or none of the fun's light to us, but the planes of the ring reflect the light in the same manner that the planet itself does; and if we suppose the diameter of Saturn to be divided into three equal parts, the diameter of the ring is about seven of these parts. The ring is detached from the body of Saturn in fuch a manner, that the distance between the innermost part of the ring and the body is equal to its breadth. If we had a view of the planet and his ring, with our eyes, perpendicular to one of the planes of the latter, we should fee them as in fig. 80. : but our eye is never fo much elevated above either plane as to have the vifual ray stand at right angles to it, nor indeed is it ever elevated more than about 30 degrees above it; fo that the ring, being commonly viewed at an oblique angle, appears of an oval form, and through very good telescopes double, as represented fig. 18. and 153. Both the outward and inward rim is projected into an ellipsis, more or less oblong according to the different degrees of obliquity with which it is viewed. Sometimes our eye is in the plane of the ring, and then it becomes invisible; either because the outward edge is not fitted to reflect the fun's light, or more probably because it is too thin to be feen at fuch a distance. As the plane of this ring keeps always parallel to itself, that is, its fituation in one part of the orbit is always parallel to that in any other part, it disappears twice in every revolution of the planet, that is, about once in 15 years; and he sometimes appears quite round for nine months together. at eacher times, the distance betwist the body of the and the ring is very perceptible; infomuch that through the opening, and supposed him to have

been the only person who ever saw a fight so rare, as Appearanthe opening though certainly very large, appears very ces of the fmall to us. When Saturn appears round, if our en Bodiesthre be in the plane of the ring, it will appear as a dark Teleicopes line across the middle of the planet's disk; and if our eye be elevated above the plane of the ring, a shadowy belt will be vifible, caused by the shadow of the ring as well as by the interpolition of part of it betwist the eye and the planet. The fladow of the ring is broadest when the sun is most elevated, but its obscure parts appear broadest when our eye is most elevated above the plane of it. When it appears double, the ring next the body of the planet appears brightest; when the ring appears of an elliptical form, the parts about the ends of the largest axis are called the anse, as has been already mentioned. These, a little before and after the disappearing of the ring, are of unequal magnitude: the largest ansa is longer visible before the planet's round phase, and appears again sooner than the other. In the first of October 1714, the largest ansa Ring of Sawas on the east fide, and on the 12th on the west side turn proof the disk of the planet, which makes it probable that bably has a the ring has a rotation round an axis: but whether or revolution not this is the case with Saturn himfall has not been on its axis. not this is the case with Saturn himself has not been discovered, on account of the deficiency of spots by which it might be determined. He has indeed two Belts difbelts, discovered with very long telescopes, which ap-covered on pear parallel to that formed by the edge of the ring Satura. above-mentioned; but thefe are rectilinear when the ring appears elliptic, as fig. 8s. and feem to be In 1683, however, Dom, Caffini and permanent. Fatio perceived a bright fireak upon Saturn, which was not permanent like the dark belts, but was wishle one day and disappeared the next, when mother came into view near the edge of his disk. This induced Cassini to suppose, that Satura might have a registion round his axis; but the distance of this planet is the great, that we can fearce hope to determine his reve-

The aftronomer-royal (Dr Maikelyne) informs us: of this disappearance in 1789, and re-appearance in 1700, in the following manner: " On May 3d and August 26th 1789, the plane of Saturn's ring will pals through the earth; on October 11th it will pals through the fun: and January 29th 1790 it will again pals through the earth. Hence, and supposing with M. de la Lande that the ring is but just visible with the best telescopes in common use, when the sun is elevated 3' above its plane, or 3 days before the plane passes through the fune and when the curth is elevated 21' above the plane, or one day from the earth's pailing it, the phenomena of disappearance and re-appearance may be expected to take place as follows:

lution to accurately as that of the others. It will

1796. Saturn is fill better attended than Jupiter (fee fig. 18. and 186.); having, besides the ring above-mentioned, no fewer than five moons continually circulating round him. The first, at the distance of 2.097 semidiameters of his ring, and 4.893 of the planet itself, performs its revolution in 1d. 21h. 18' 27"; the fecond, at 2.686 femidiameters of the ring, and 6.268 of Saturn, revolves in 2d. 17h. 41' 22"; the third, at the diflance of 8.752 femidiameters of Saturn, and 3.752 of the ring, in 4d. 12h. 25' 12"; the fourth, called the Huygenian fatellite, at 8.698 femidiameters of the ring, and 20.205 of Saturn, revolves in 15d. 22h. 41' 12"; while the fifth, placed at the vast distance of 59.154 semidiameters of Saturn, or 25.348 of his ring, does not perform its revolution in less than 79d. 7h. 47' 00". The orbits of all these satellites, except the fifth, are nearly in the same plane, which makes an. angle with the plane of Saturn's orbit of about 91°; and by reason of their being inclined at such large angles, they cannot pass either across their primary or behind it with respect to the earth, except when very near their nodes; so that eclipses of them happen much more seldom than of the satellites of Jupiter. There is, however, an account in the Philos. Transact. of an occultation of the fourth satellite behind the body of Satural, and there is a curious account by Cassini in the Memoirs of the Royal Academy for 1692, of a fixed flar being covered by the fourth fatellite, fo that for 13 minutes they appeared both as one star. By reason of their extreme smallness, these satellites cannot be seen unless the air is very clear; and Dom. Cassini for several years observed the fifth satellite to grow less and less as it went through the eastern part of its orbit until it became quite invisible, while is the western part it gradually became more and more bright until it arrived at its greatest splendour. "This phenomenon (fays Dr Long) cannot be better accounted for than by supposing one half of the surface of this satellite to be unfit to reflect the light of the fun in fufficient quantity to make it visible, and that it turns round its axis nearly in the same time as it revolves round its primary; and that, by means of this rotation, and keeping always the same face toward Saturn, we upon the earth may, during one half of its periodical time, be able to fee successively more and mure of its bright fide, and during the other half of its period have more and more of the spotted or dark side turned toward us. In the year 1705, this fatellite unexpectedly became visible in all parts of its orbit through the very same telescopes that were before often made use of to view it in the eastern part without success: this shows the spots upon this fatellite, like those upon Jupiter and some other of the primary planets, are not permanent, but Subject to change."

8. With regard to the Georgium Sidus, still less is

known than of Saturn. Its apparent magnitude is so Appearance finall, that it can feldom be feen with the naked eye; ces of the and even with the telescope it appears but of a few se-Bodiesthra conds diameter. It is attended by two fatellites at the Telefcopes. proportional distances marked in fig. 82. according to the observations of Mr Herschel; but he had not an 109 opportunity of observing them long enough to deter-Georgium mine their periodical times with exactness; though he Sidus atsupposes the innermost to perform its revolution in two satelabout eight days and three quarters, the other in thir-lites. teen days and a half.

9. The comets, viewed through a telescope, have a Of the covery different appearance from any of the planets. mcts. The nucleus, or star, seems much more dim. Sturmius tells us, that observing the comet of 1680 with a telefcope, it appeared like a coal dimly glowing; or a rude mass of matter illuminated with a dusky fumid light, less sensible at the extremes than in the middle; and not at all like a flar, which appears with a round disk

and a vivid light. Hevelius observed of the comet in 1661, that its body was of a yellowish colour, bright and conspicuous, but without any glittering light. In the middle was a dense ruddy nucleus, almost equal to Jupiter. encompassed with a much fainter, thinner matter .-February 5. The nucleus was fomewhat bigger and brighter, of a gold colour, but its light more dusky than the rest of the stars; it appeared also divided into a number of parts.—Feb. 6. The nuclei still appeared, though lefs than before. One of them on the left fide of the lower part of the difk appeared to be much denser and brighter than the rest; its body round, and reprefenting a little lucid flar; the nuclei still encompassed with another kind of matter .- Feb. 10. The nuclei more obscure and confused, but brighter at top than at bottom. Feb. 13. The head diminithed much both in brightness and in magnitude.-March 2. Its roundness a little impaired, and the edges lacerated .- March 28. Its matter much difperfed; and no distinct nucleus at all appearing.

Wiegelius, who saw through a telescope the comet of 1664, the moon, and a little cloud illuminated by the fun, at the fame time, observed that the moon appeared of a continued luminous furface, but the comet very different, being perfectly like the little cloud enlightened by the fun's beams.

The comets, too, are to appearance furrounded with Their atatmospheres of a prodigious fize, often rifing ten times mospheres higher than the nucleus. They have often likewise and phase different phases, like the moon.

"The head of a comet (fays Dr Long) to the eye, Dr Long's unaffifted by glasses, appears sometimes like a cloudy account of star; sometimes shines with a dull light like that of them. the planet Saturn : some comets have been faid to equal, fome to exceed, flars of the first magnitude; some to have surpassed Jupiter, and even Venus; and to have cast a shadow as Venus sometimes does.

"The head of a comet, feen through a good telescope, appears to consist of a solid globe, and an atmolphere that furrounds it. The folid part is frequently called the nucleus: which through a telescope is eafily diffinguished from the atmosphere or hairy appearance.

"A comet is generally attended with a blaze or tail, whereby it is diffinguished from a star or planet;

ces of the comet of 12 Oz 8.

Appearan- as it is also by its motion. Sometimes the tail only of cos of the a comet has been visible at a place where the head has Bodiesthro, been all the while under the horizon; fuch an appear-Pelefcopes, ance is called a beam.

"The nucleus of the comet of 1618 is faid, a few days after coming into view, to have broken into three Appearan- or four parts of iregular figures. One observer compares them to fo many burning coals; and fays they changed their fituation while he was looking at them, as when a person stirs a fire; and a few days after were broken into a great number of fmaller pieces. Another account of the same is, that on the 1st and 4th of December, the nucleus appeared to be a round, folid, and luminous body, of a dufky lead colour, larger than any flar of the first magnitude. On the 8th of the same month it was broken into three or four parts of irregular figures; and on the 20th was changed into a cluster of small stars.

111 Phenomena of their stails

" As the tail of a comet is owing to the heat of the fun, it grows larger as the comet approaches near to, and shortens as it recedes from, that luminary. If the tail of a comet were to continue of the fame length, it would appear longer or shorter according to the different views of the spectator; for if his eye be in a line drawn through the middle of the tail lengthwife, or nearly fo, the tail will not be diffinguished from the rest of the atmosphere, but the whole will appear round; if the eye be a little out of that line, the tail will appear short as in fig. 83.; and it is called a bearded comet when the tail hangs down towards the horizon, as in that figure. If the tail of a comet be viewed fidewise, the whole length of it is feen. It is obvious to remark, that the nearer the eye is to the tail, the greater will be the apparent length thereof.

"The tails of comets often appear bent, as in fig. 84 and 85. owing to the relistance of the ether; which, though extremely small, may have a sensible effect on fo thin a vapour as the tails confift of. This bending is feen only when the earth is not in the plane of the orbit of the comet continued. When that plane paffes through the eye of the spectator, the tail appears straight,

as in fig. 86, 87.

"Longomontanus mentions a comet, that, in 1618, December 10. had a tail above 100 degrees in length; which shows that it must then have been very near the earth. The tail of a comet will at the same time appear of different lengths in different places, according as the air in one place is clearer than in another. need not be mentioned, that in the same place, the difference in the eyes of their spectators will be the cause of their difagreeing in their estimate of the length of

the tail of a comet.

115

D fference

between

the obser-

" Hevelius is very particular in telling us, that he observed the comet of 1665 to cast a shadow upon the tail; for in the middle thereof there appeared a dark line. It is somewhat surprising, that Hooke should and Hooke, be positive in affirming, on the contrary, that the place where the shadow of the comet should have been, if there had been any shadow, was brighter than any other part of the tail. He was of opinion that comets have some light of their own: His observations were made in a hurry; he owns they were short and transito-

Hevelius's were made with fo much care, that ere is more reason to depend upon them. Dom. Casand abserved, in the tail of the comet of 1680, a darkness in the middle; and the like was taken notice of Appearanby a curious observer in that of 1744.

"There are three comets, viz. of 1680, 1744, and Bodiesthro 1759, that deferve to have a farther account given of Telescopes. them. The comet of 1680 was remarkable for its near approach to the fun; fo near, that in its perihelion it was not above a fixth part of the diameter of Account o that luminary from the surface thereof. Fig. 85, the counct o taken from Newton's Principia, represents so much of 1680. the trajectory of this comet as it passed through while it was visible to the inhabitants of our earth, in going from and returning to its perihelion. It flows also the tail, as it appeared on the days mentioned in the figure. The tail, like that of other comets, increased in length and brightness as it came nearer to the sun; and grew shorter and fainter as it went farther from him and from the earth, till that and the comet were

too far off to be any longer visible.

"The comet of 1744 was first seen at Lausanne in of that of Switzerland, Dec. 13. 1743. N. S. From that time 1744. it increased in brightness and magnitude as it was coming nearer to the sun. The diameter of it, when at the diffance of the Iun from us, mensured about one minute; which brings it out equal to three times the diameter of the earth. It came so near Mercury, that, if its attraction had been proportionable to its magnitude, it was thought probable it would have disturbed the motion of that planet. Mr Betts of Oxford, however, from some observations made there, and at Lord Macclesfield's observatory at Sherburn, found, that when the comet was at its leaft diffance from Mercury, and almost twice as near the fun as that planet was, it was ftill diftant from him a fifth part of the diftance of the fun from the earth; and could therefore have no effect upon the planet's motions. He judged the comet to be at least equal in magnitude to the earth. He fays, that in the evening of Jan. 23. this comet appeared exceedingly diffinel and bright, and the diameter of its nucleus nearly equal to that of Jupiter. Its tail extended above 16 degrees from its body; and was in length, supposing the sun's parallax 10", no less than 23 millions of miles. Dr Bevis, in the month of May 1744, made four observations of Mercury, and found the places of that planet, calculated from correct tables, differed so little from the places observed, as to show that the comet had no influence upon Mercury's

" The nucleus, which had before been always round, on the 10th of February appeared oblong in the direction of the tail, and feemed divided into two parts; by a black stroke in the middle. One of the parts had a fort of beard brighter than the tail; this beard was furrounded by two unequal dark strokes, that feparated the beard from the hair of the comet. This odd phenomena disappeared the next day, and nothing was feen but irregular obscure spaces like smoke in the middle of the tail; and the head refumed its natural form. Feb. 15. the tail was divided into two branches; the eastern part about seven or eight degrees long, the western 24. On the 23d, the tail began to be bent; it showed no tail till it was as near to the sun as the orbit of Muts; the tail grew longer as it approached nearer the fun; and at its greatest length was computed to equal a third part of the distance of the earth from the lun. Fig. 84. is a view of this comet, taken

motion.

Appearan- by an observer at Cambridge. I remember that in ces of the viewing it I thought the tail scemed to sparkle, or vi-Celeftial Bodies thro' brate luminous particles. Hevelius mentions the like Telescopes, in other comets; and that their tails lengthen and Inorten, while we are viewing.

118 nict of 1759.

"The comet of 1759 did not make any confidera-Of the co- ble appearance by reason of the unfavourable situation of the earth all the time its tail might otherwise have been conspicuous; the comet being then too near the fun to be feen by us; but deferves our particular confideration, as it was the first that ever had its return foretold." See the following Section.

Hevelius gives pictures of comets of various shapes; as they are described by historians to have been like a sword, a buckler, a tun, &c. These are drawn by fancy only, from the description in words. He gives, however, also pictures of some comets, engraved by his own hand from the views he had of them through a very long and excellent telescope. In these we find changes in the nucleus and the atmosphere of the same comet. The nucleus of the comet of 1661, which in one observation appeared as one round body, as it is represented in fig. 87. in subsequent views seemed to confift of feveral smaller ones separated from one another, as in fig. 86. The atmosphere surrounding the nucleus, at different times, varied in the extent thereof; as did also the tail in length and breadth. The nuclei of other comets, as has already been obferved, have fometimes phases like the moon. Those of 1744 and 1769 had both this kind of appearance.

119 Mumbers of fixed flare increased by tele-Scopes.

See fig. 34. lescopes, appear not at all magnified, but rather diminished in bulk; by reason, as is thought by some, that the telescope takes off that twinkling appearance they make to the naked eye; but by others more probably, that the telescopic tube excludes a quantity of the rays of light, which are not only emitted from the particular firs themselves, but by many thousands more, which falling upon our eyelids and the aerial particles about us, are reflected into our eyes fo firongly as to excite vibrations, not only on those points of the retina where the images of the stars are formed, but also ia other points at the same distance round about. This without the telescope makes us imagine the stars to be much bigger than when we see them only by a few rays coming directly from them, fo as to enter our eyes without being intermixed with others. The number of stars appears increased prodigiously through the telescope; 70 stars have been counted in the confellation called Pleiades, and no fewer than 2000 in that of Orion. The late improvements of Mr Herschel, bowever, have shown the number of stars to be exoccdingly beyond even what the discoveries of former aftronomers would induce us to suppose. He has also hown, that many which to the eye, or through ordipary glasses, appear fingle, do in fact confift of two or more flars; and that the galaxy or milky way owes its light entirely to multitudes of small stars placed fo olose, that the naked eye, or even ordinary telescopes, cannot discover them.

Of the ne-

He has shown also, that the nebulæ, or small whitish specks, discoverable by telescopes in various parts of the beavens; are owing to the same cause. Former aftronomers could only reckon 103; but Mr Herschel has Conclusion discovered upwards of 1250. He has also discovered a from the species of them, which he calls planetary nelula, on Appearance account of their brightness and thining with a welldefined difk, being also capable of being magnified more than the fixed flars.

SECT. III. Conclusions from the foregoing Appearances.

THE conjectures which have been formed concerning the nature of the celeftial bodies are fo numerous, that a recital of them would fill a volume; while at the fame time many of them are so ridiculous, that absurdity itself would seem almost to have been exhausted on this subject.

1. As a specimen of what were the opinions of the ancient philosophers concerning the nature of the fun, Opinions of it may suffice to mention, that Anaximander and Anaxi-the ancients menes held, that there was a circle of fire all along the concerning heavens, which they called the circle of the fun; between the earth and this fiery circle was placed another circle of some opaque matter, in which there was a hole like the mouth of a German flute. Through this hole the light was transmitted, and appeared to the inhabitants of this earth as a round and diffined body of fire. The eelipfes of the fun were occasioned by stopping this hole.

We must not, however, imagine, that the opinions of all the ancients were equally abfurd with those of Anaximander and Anaximenes. Many of them had. more juit notions, though very imperfect and obscure. Anaxagoras held the fun to be a fiery globe of fome folid fubflance, bigger than Peloponnefus; and many of the moderns have adopted this notion, only increafing the magnitude of the globe prodigiously. Sir Ifaac Newton has proposed it as a query, Whether the Of Sir Ifaac fun and fixed stars are not great Larths made vehe-Newton. mently hot, whose parts are kept from furing away by the vast weight and density of their superincumbent atmospheres, and whose heat is preserved by the prodigious action and re-action of their parts upon one another? But though Sir Isaac has proposed this as a query, and taken the exiltence of a folar atmosphere for Of the exgranted, there have yet been no proofs adduced in favour illence of a of that opinion besides those of analogy and probability. folar atmo-There is, however, an appearance in the heavens term-fphere. ed the femita luminofa, or nodiacal light, which is now generally supposed to be owing to the fun's atmosphere. Semita lu-This was first discovered by Dom. Cassini in 1683. It minofa, eris something like the milky way, a faint twilight, or roducal the tail of a comet, thin enough to let stars be seen through it, and feems to furround the fun in the form of a lens, the plane whereof is nearly coincident with that of the fun's equator. It is feen stretched along the zodiac, and accompanies the fun in his annual motion through the twelve figns. Each end terminates in an angle of about 21°: the extent of it in length from either of the angular points varies from 50 to 100°; it reaches beyond the orbit of Venus, but not fo fare as that of the earth. The breadth of it near the horizon is also various; from 12 almost to 30°: near the fun, where it may reasonably be supposed to be broadest, it cannot be feen. This light is weakest in the morning and flrongest at night; disappearing in full.

moonlight.

Appearances.

anchilions moonlight, or in strong twilight, and therefore is not from the at all visible about midsummer in places so near either of the poles as to have their twilight all the night long, but may be feen in those places in the middle of winter both morning and evening, as it may in places under and near the equator all the year round. In north latitude it is most, conspicuous after the evening twilight about the latter end of February, and before the morning twilight in the beginning of October; for at those times it stands most erect above the horizon, and is therefore clearest from the thick vapours of the twilight. Befides the difference of real extension of this light in length and breadth at different times, it is diminished by the nearness of any other light in the sky; not to mention that the extent of it will be differently determined by different spectators according to the goodness of their eyes.

Caffini's exmenon.

126

Supposes

fpots and

zodia.al

light.

Cassiui, inquiring into the cause of this light, says stanation of first, that it might be owing to a great number of fmall planets furrounding the fun within the orbit. of Venus; but foon rejects this for what he thinks a more probable folution, viz. that as by the rotation of the fun some gross parts are thrown up on his furface, whereof spots and nebulofities are formed; fo the great rapidity wherewith the equatorial parts are moved, may throw out to a confiderable distance a number of particles of a much finer texture, of fufficient density to reflect light: now, that this light was caused by an emanation from the fun, similar to that of the spots, he thought probable from the folsome analo-lowing observation: That after the year 1688, when my between this light began to grow weaker, no spots appeared upon the fun; whereas, in the preceding years, they were frequently feen there; and that the great inequality in the intervals between the times of the appearances of the folar spots has some analogy to the irregular returns of weakness and strength in this light, in like circumstances of the constitution of the air, and of the darkness of the sky. Cassini was of opinion that this light in the zodiac, as it is subject to great increase at one time and diminution at another, may fometimes become quite imperceptible; and thought this was the case in the years 1665, 1672, and 1681, when he faw nothing of it, though he furveyed with great attention those parts of the heaven where, according to his theory, it must have appeared if it had been as visible then as it was in others. He cites also passages out of several authors both ancient and modern, which make it probable that it had been feen both in former and later ages, but without being fuf-ficiently attended to, or its nature inquired into. It had been taken for the tail of a comet, part of the twilight, or a meteor of fhort continuance; and he was fully convinced of its having appeared formerly, from a paifage in an English book of Mr Childrey's, printed in 1661. This passage is as follows:

"There is something more that we would recommend to the observation of the mathematicians, namely, that in the month of February, and a little before and after it (as I have observed for several years) about fix o'clock in the evening, when the twilight has entirely left the horizon, a path of light tending from the twilight towards the Pleiades, and touching them This path is to be seen when the weather is clear, but best of all when the moon does not shine." The same Conclusions appearance is taken notice of in Gregory's aftronomy, from the and there expressly attributed to the sun's atmosphere. Ioregoing Appearan-With regard to the solar spots, Dr Long informs ces-

us, that "they do not change their places upon the fun, but adhere to his furface, or float in his atmofphere, very near his body; and if there be 20 fpots Dr Long's or fæculæ upon him at a time, they all keep in the same opinion of or recure upon min at a time, to the reflect to one another; and, as long as fpots. they laft, are carried round together in the fame manner: by the motion of the fpots therefore we harn, what we should not otherwise have known, that the fun is a globe, and has a rotation about his axis." Notwithstanding this he tells us afterwards, " The spots, generally speaking, may be said to adhere to the sun, or to be fo near him as to be carried round upon him uniformly; neverthelefs, fometimes, though rarely, a fpot has been feen to move with a velocity a little different from the rest; spots that were in different parallel, have appeared to be carried along, not keeping always the fame distance, but approaching nearer to each other; and when two spots moved in the same parallel, the hindmost has been observed to overtake and pass by the other. The revolution of spots near the equator of the fun is shorter than of those that are

more distant from it." The apparent change of fhape in the spots, as they of the fun's approach the circumference of the difk, according to revolution our author, is likewife a proof of the fun's rotation on his axis, round his axis, and that they either adhere to the furface of the luminary, or are carried round his atmo-

fphere very near his furface. "The rotation of the fun (faye Dr Long) de known, we may confider his axis and poles, and their fituation; as also his equator, or a circle imagined to be drawn upon that luminous globe equally distant from his poles; we may also imagine teller circles drawn thereon, parallel to his equator.

" The rotation of the fun is according to the order of the figns ; that is, any point on the furface of that vall globe turns round to as to look incerflively at Aries, Taurus, Gemini, &c. which is allothe way that all the primary planets are carried round him, though each of them in a plane a little different from that of the reft. We must likewise observe, that the plane of the fun's equator produced, does not coincide with the heliocentric orbit of any of the planets, but cuts every one of them at a small angle; it is nessest to coincidence with the orbit of Venus.

The fun being a globe at a great distance from us, we always fee nearly one half of that globe at a time; but the visible half is continually changing, by the rotation of the fun, and the revolution of the earth in her orbit. To speak accurately, we do not see visible part quite half the fun's globe at a time; we want fo much of the fun's of it as the fun's apparent diameter amounts to, which globe less at his mean distance is about 32 minutes; so much is than the the diameter of the visible part of the fun greater than invisible. that of the invilible part; for this reason a spot may be about two hours longer invisible than visible.

"The time between the entrance of a fpot upon the disk and its exit therefrom, gives us nearly half the apparent period of the fun's rotation, which is ufinally about 13 days ; a spot that, after passing the disk and disappearing, returns again, gives the whole

Conclusions time, but not with precision; because the sport may from the perhaps not keep all the while exactly in the same foregoing place, but have some floating motion of its own upon the furface of the fun. Dom. Cassini, taking notice that several spots had often appeared in the same parallel, thought that fome particular places of the fun might be more disposed than others to supply the matter of these spots; and if so, that they would not move far from the place of their origin, just as the smoke of Mount Ætna, if it could be seen from the sun, would appear always to return to the same place of the disk of the earth once every 24 hours, very nearly; fometimes a little fooner, fometimes a little later, according as the smoke was driven by the wind from the place of its eruption. In confequence of this supposition, he compared several large intervals between the appearances of spots carried in the same parallel, which he judged to be returns of the same spots arising out of the same place on the surface of the sun, and found that 27 days 22 hours and 20 feconds was a common measure of those intervals very nearly: this therefore, he thought the most proper period to be taken for an apparent revolution of the folar spots, and consequently of the sun himself as seen from the earth. These observations were made in April and May, nearly in the same time of the year, and therefore are not much affected by the inequality of the earth's motion. The fame period is confirmed by Dom. Cassini.

How to find The time of the apparent revolution of a fpot being known, the true time of its going round upon the fun time of a rooms, be thus found: In fig. 3. the arc AC, which in volution of the month of May, the earth goes through in her orning at the start of the month of May, the earth goes through in her orning 3. Bit is 27 days 12 hours and 20 minutes, is 26° 22'; the arc ac being equal to AC: the apparent revolution of a spot is the whole circle a b c d, or 360°, with the *ddition of the arc ac of 26° 22', which makes 386° 22': then fay, as 486.22 is to 27d. 12h. 20'; fo is 360° to 25d. 15h. 16'; the true time of the rotation of the

fun, as it would be feen from a fixed flar.

The angle of interfection of the fun's equator with the ecliptic is but small, according to Scheiner being never more than 8°, nor less than 6°; for which reafon he settled it at 7°, though Cassini makes it 73. Sun's nodes This plane continued cuts the ecliptic in two opposite and limits. points, which are called the fun's nodes, being 80 of II, and 8° of w; and two points in the ecliptic, 90° from the nodes, may be called the limits. These are 8° of x and 8° of my. When the earth is in either of these nodes, the equator of the fun, if visible, would appear as a ftraight line; and, by reason of the vast distance of the fun from us, all his parallels would likewife appear as straight lines; but in every other situation of the earth, the equator and parallels of the fun would, if visible, appear as eclipses growing wider the farther the earth is from the nodes, and widest of all when the earth is in one of her limits.

> " In the present age (says Dr Long), on the 18th of May, the earth is in the 8° of the nodes of the fun, and consequently the fun's equator and parallels, if visible, would appear as straight lines, fig. 92. From that time the fun's equator, and every parallel, begin to appear as half of an ellipsis, convex or swelling towards the fouth, and growing wider every day to the 20th of August, when it is at the widest, as in fig. 93. the earth being then in the 89 of X, one of Vol. II. Part II.

the limits. Immediately after, the apparent curvature Conclude of the fun's equator and parallels continually decreases from the to the 19th of November, when they again appear as foregoing fraight lines, the earth being then in the other node. From that time the equator of the sun and parallels. become elliptical, convex towards the north; their curvature continually increasing to the 15th of February, when the earth is arrived at the other limit; and their curvature then decreases continually to the 18th of May, when they again appear as straight lines. Every spot is carried round the sun in his equator, or in a parallel; therefore the apparent motion of the spots upon the sun is rectilinear every year in May and November, at all other times elliptical." See fig. 16, 17. where the paths of some solar spots are delineated by Mr Dunn, in a manner feemingly inconfistent with what is just now delivered from Dr Long. From a farther confideration of the nature of the paths described by the folar spots, the Doctor concludes that their appearance may be retarded about four hours by the

unequal motion of the earth in its orbit.

The nature and formation of the folar spots have been Of the nathe subject of much speculation and conjecture. Some ture and have thought that the sun is an opaque body, moun of the solar tangent and the sum of the solar tangent and tang tainous and uneven as our earth is, covered all over foots. with a fiery and luminous fluid: that this fluid is fubject to ebbing and flowing, after the manner of our tides, so as sometimes to leave uncovered the tops of rocks or hills, which appear like black spots; and that the nebulofities about them are caused by a kind of froth. Others have imagined, that the fluid which fends us fo much light and heat, contains a nucleus or folid globe, wherein are several volcanoes, that, like Ætna or Vesuvius, from time to time cast up quantities of bituminous matter to the furface of the fun, and form those spots which are feen thereon; and that as this matter is gradually confumed by the luminous fluid. the spots disappear for a time, but are seen to rife again in the same places when those volcanoes cast up new matter. A third opinion is, that the fun confifts of a fiery luminous fluid, wherein are immerfed feveral opaque bodies of irregular shapes; and that these bodies, by the rapid motion of the fun, are fometimes buoyed or raised up to the surface, where they form the appearance of spots, which seem to change their shapes according as different sides of them are presented to the view. A fourth opinion is, that the fun coufifts of a fluid in continual agitation; that, by the rapid motion of this fluid, some parts more gross than the reft are carried up to the furface of the luminary, like the scum of melted metal rising up to the top in a furnace: that these scums, as they are differently agitated by the motion of the fluid, form themselves into those spots we see on the solar disk; and, besides the optical changes already mentioned, grow larger, are diminished in their apparent magnitude, recede a little from, or approach nearer to, each other, and are at last entirely diffipated by the continual rapid motion of the fluid, or are otherwise confumed or absorbed.

In the 64th volume of the Philosophical Transac-Spots of th tions, Dr Wilson advances a new opinion concerning sun suppothe folar spots, viz. that they are hollows in the fur. fed by Dr face of the luminary. "All the foregoing appearances Willon to (fays he), when taken together, and when duly confidered, feem to prove in the most convincing manner,

ure of

fun.

148.07

enclusions that the nucleus of this spot (December 1769) was from the confiderably beneath the level of the fun's spherical furinregoing face.

C£8.

"The next thing which I took into confideration was, to think of fome means whereby I could form an estimate of its depth. At the time of the observation. I had, on December 12th, remarked that the breadth of the fide of the umbra next the limb was about 14"; but, for determining the point in question, it was also requilite to know the inclination of the shelving side of the umbra to the fun's spherical surface. And here it occurred, that, in the case of a large spot, this would in some measure be deduced from observation. For, at the time when the fide of the umbra is just hid, or begins first to come in view, it is evident, that a line joining the eye and its observed edge, or uppermost limit, coincides with the plane of its declivity. By measuring therefore the distance of the edge from the limb, when this change takes place, and by representing it by a projection, the inclination or declivity may in some measure be ascertained. For in fig. 27. let ILDK be a portion of the sun's limb, and ABCD a section of is method the spot, SL the sun's semidiameter, LG the observed

measur- distance from the limb, when the side of the umbra changes; then will the plane of the umbra CD coincide with the line EDG drawn perpendicular to SL at the point G. Let FH be a tangent to the limb at the

point D, and join SD.

" Since GL, the versed fine of the angle LSD, is given by observation, that angle is given, which by the figure is equal to FDE or GDH; which angle is therefore given, and is the angle of inclination of the plane of the umbra to the fun's spherical surface. . In the small triangle therefore CMD, which may be confidered as rectangular, the angle MDC is given, and the fide DC equal to AB is given nearly by observa-tion; therefore the fide MC is given, which may be regarded as the depth of the nucleus without any ma-

terial error.

" I had not an opportunity, in the course of the foregoing observations, to measure the distance GL, not having feen the spot at the time when either of the fides of the umbra changed. It is, however, certain, that when the fpot came upon the disk for the second time, this change happened some time in the night between the 11th and 12th of December, and I judge that the distance of the plane of the umbra, when in a line with the eye, must have been about 1' 55" from the fun's castern limb; from which we may fafely conclude, that the nucleus of the spot was, at that time, not less than a femidiameter of the earth below the level of the fun's spherical surface, and made the bottom of an amazing cavity, from the furface downwards, whose other dimensions were of much greater extent."

Having thus demonstrated that the solar spots are conjeces con- vast cavities in the sun, the Doctor next proceeds to ning the offer fome queries and conjectures concerning the nature of the fun himfelf, and to answer some objections to his hypothesis. He begins with asking, Whether it is not reasonable to think, that the vast body of the fun is made up of two kinds of matter very different in their qualities ; that by far the greatest part is folid and dark; and that this dark globe is encompassed with a thin covering of that resplendent substance, from nich the sun would seem to derive the whole of his

visifying heat and energy ?- This, if granted, will at Conclusion ford a latisfactory foliation of the appearance of spotas from the because, if any part of this resplendent surface shall be foregoing by any means displaced, the dark globe must necessarily appear; the bottom of the cavity corresponding to the nucleus, and the shelving sides to the umbra. The shining substance, he thinks, may be displaced by the action of some elastic vapour generated within the substance of the dark globe. The vapour, swelling into fuch a volume as to reach up to the furface of the luminous matter, would thereby throw it aside in all directions: and as we cannot expect any regularity in the production of fuch a vapour, the irregular appearance and disappearance of the spots is by that means accounted for; as the reflux of the luminous matter must always occasion the dark nucleus gradually to decrease, till at last it becomes indistinguishable from the rest of the surface.

Here an objection occurs, viz. That, on this suppofition, the nucleus of a spot whill on the decrease should always appear nearly circular, by the gradual descent of the luminous matter from all fides to cover it. But to this the Doctor replies, that in all probability the furface of the dark globe is very uneven and mountainous, which prevents the regular reflux of the thining matter. This, he thinks, is rendered very probable by the enormous manatains and cavities which are observed in the moon; and why, says he, may there not be the same on the surface of the sun? He thinks his hypothesis also confirmed by the dividing of the nucleus into several parts, which might arise from the luminous matter flowing in different channels in the bottom of the hollow The appearance of the unthra atter the nucleus is gone, he thinks, may be owing to a cavity remaining in the luminous matter, though the dark globe is entirely covered.

As to a motion of the spots, distinct from what they are supposed to receive from the notation of the fun. round his axis, he fays he never could observe any, except what might be attributed to the enlargement or diminution of them when in the neighbourhood of one another. "But (fays he) what would farther contribute towards forming a judgment of this kind, is the apparent alteration of the relative place, which must arife from the motion across the disk on a spherical furface a a circumflance which I am uncertain if it has.

been sufficiently attended to."

The above mentioned hypothesis, the Doctor thinks, is farther confirmed by the disappearance of the umbræ on the fides of fpots contiguous to one another; as the action of the elastic vapour mult necessarily drive the luminous matter away from each, and thus as it were accumulate it between them, so that no umbra can be perceived. As to the luminous matter, itself, he conjectures, that it cannot be any very ponderous fluid, but that it rather resembles a dense fog which broods on the furface of the fun's dark body. His general conclusion we shall give in his own words:-

"According to the view of things given in the foregoing queries, there would feem to be fomething very extraordinary in the dark and unignited state of the great internal globe of the fun. Does not this feem to indicate that the luminous matter that encompasses it derives not its splendour from any intensity of heat? For, if this were the case, would not the pasts under-

forgoing Aperan

Confusion neath, which would be perpetually in contact with that fron the glowing matter, he heated to fuch a degree as to become luminous and bright? At the same time it must be confessed, that although the internal globe was in reality much ignited, yet when any part of it forming the nucleus of a spot is exposed to our view, and is feen in competition with a substance of such amazing fplendour, it is no wonder that an inferior degree of light should, in these cases, be unperceivable.

x 36 Experiment

" In order to obtain some knowledge of this point, proposed in I think an experiment might be tried, if we had an opportunity of a very large spot, by making a contriconfirm his vance in the eye-piece of a telescope, whereby an obhypothess, ferver could look at the nucleus alone with the naked eye, without being in danger of light coming from any other part of the fun. In this case, if the observer found no greater splendour than what might be expected from a planet very near the fun, and illumined by as much of his furface as corresponds to the spot's umbra, we might reasonably conclude, that the solar matter, at the depth of the nucleus, is in reality not ignited. But from the nature of the thing, doth there feem any neceffity for thinking that there prevails fuch a raging and fervent heat as many have imagined? It is proper here to attend to the diffinction between this shining matter of the fun and the rays of light which proceed from it. It may perhaps be thought, that the reaction of the rays upon the matter, at their emillion, may be productive of a violent degree of heat. But whoever would urge this argument in favour of the fun being intenfely hented, as arising from the nature of the thing, ought to confider that all polified bodies are less and less dispoled to be heated by the action of the rays of light, in proportion as their farfaces are more polished, and as their powers of reflection are brought to a greater degree of perfection. And is there not a firong analogy betwirt the reaction of light upon matter in cales where it is reflected, and in cafes where it is emitted?"

To this account of the folar spots, some objectious have been made, particularly by Mr Wollaston, in the Philosophical Tranfactions, and M. de la Lande in the Memoirs of the Academy of Sciences; and to these Dr Wilson replied in the Philosophical Transactions for

1783, to the following purpole:

" Fiell of all (fays he) it has been urged, as an objection of great weight, that the absence of the umbra on one fide, where spots are near the limb, is not always constant; and of this I was sufficiently aware, having stated three cales from my own observation, when I did not perceive this change to take place. The reverend Francis Wollaston is the only person who, in the Philosophical Transactions, has bestowed any remarks on my publication; and though he acknowledges that the umbra generally changes in the manner I have determined, yet he expresses a difficulty as to my conclusion, on account of this circumstance not obtaining univerfally. Under similar expressions, M. de la Lande produces from his own observations, which appear to have been long continued, only three cases of the same kind, and four more from the ancient observations of M. Cassini and De la Hire. In regard to these last, I am not sure if such obsolete ones ought to be referred to in a question of the present kind. These excellent observers, entertaining no thought that any thing of moment depended upon a nice atten-

tion to the form of the spots, might easily overlook Conclusion less obvious circumstances, especially when they were from the found near the limb. We may add farther, that even foregoing when they were so fituated, they retain the umbra at Appearance both ends; and that whole fide of it which lies farthest from the centre of the disk, and these parts in the aggregate, they might fometimes mistake for the umbra as not deficient in any particular place. But, even admitting the anomaly we at prefent confider to be much more frequent than can be contended for, still such cases can only be brought as so many exceptions to the general law or uniformity of appearance, from which the condition of by far the greatest number of spots is most undeniably deduced. The utmost, therefore, that can be alleged is, that some few spots differ from all the rest, or from the multitude; and are not, like them, excavations in the fun. But notwithstanding thele few inflances where the umbra is not found to change, when we consider how perfectly all spots refemble one another in their most striking features, there naturally rifes fome prefumption for all under that description we have given, partaking of one common nature; and for this only difference in the phenomena depending upon fomething, which does not necessarily imply a complete generical distinction. It comes therefore to be inquired how far spots, which when near the middle of the disk appear equal and iimilar in all things, may yet differ from one another as excavations, or as possessing the third dimension of depth? and how far the peculiar circumstances by which they may difagree, can contribute to make some refift this change of the umbra when near the limb much more than others?

"In order to this, suppose two spots which occupy a space upon the fun corresponding to the equal arches GD, fig. 94. and let GM, DM, be drawn fo as to coincide with the place of the excavation in fuch a case. The breadth of the nucleus being commonly equal to that of the furrounding umbra, if the base MD of the triangle GDM conceived rectilineal, be divided in I., so as ML: LD: : MD: DG; and if through L be drawn LS parallel to DG, then will DGSL be the section of two spots having this condition; and which, as to fense, would, when far away from the limb, be equal in all apparent measures; tho' very unequal in the third dimension HE, or depth of the nucleus SL, and also in the inclination DGM of their fides parallel to the spherical surface of the sun. Now it is manifest from the construction of the figure, that the distances AB, AK, from the limb A, when the sides GS of the umbra disappear, must depend very much on the latter of these two circumstances; and when, according as the angle of inclination DGM is fmaller, the respective spot will go nearer to the limb than the other, before the fiele of the umbra GS vanishes. But these very exceptions to the general phenomena which we are at prefent examining, are of this kind; and may perhaps, from what has been now shown, proceed wholly from the shallowness and the very gradual shelving of some sew spots which break out in certain tracts of the fun's body, over which the luminous matter lies very thinly mantled.

"In order to avoid circumlocution, we may call that fide of the umbra which lies nearest the limb the nearest umbra, and the fide opposite the farthest umbra ?

to objections.

The Doc-

tor's reply

sclusions and to enter more particularly into the confideration om the now before us, let us suppose a spot of 40" over all, with its nucleus and umbra equally broad; then will the depth of the nucleus, and the apparent breadth of the nearest umbra, when the plane of the farthest comes to coincide with the vifual ray, be expressed as in the following examples, where the apparent femidiameter of the fun is supposed to be 16', and his parallax 8.5".

£	uppo vanifl	tumbra fed to h when t from	us, in	f nucle- English and se-	Apparent breadth of nearest um- bra.
1.	1	0"	4.54"	2118	8.58
II.	0	30	3.09	1442	6.02
III.	0	15	2.09	975	4.13
IV.	0	8	1.44	672	2.87

"Now because in every aspect of a spot the real breadth of either the farthest or nearest umbra must be to the projected or apparent breadth as radius to the fine of the angle which this respective plane makes with the vifual ray, it follows, that at any time before the fpot comes so near the limb as is expressed in the above examples, the apparent breadth of the nearest and furthest umbra cannot differ so much as by the quantity there let down for the apparent breadth of the nearest when the other is supposed to vanish. Regarding, therefore, the farthest and nearest umbra of the spot in Case IV. as two neighbouring visible objects which turn narrower by degrees as the spot goes towards the limb, we should undoubtedly judge that they contract as to sense alike; since, so long as the farthest could be perceived, the other cannot appear to exceed it by a quantity that we could distinguish; and by the time the former coincides with the vifual ray, the extreme nearness to the limb would prevent our forming any certain judgment of either.

" From this last example, therefore, it appears manifelt, that a spot answering to the description and conditions therein mentioned, or one a little more shallow, would approach the limb, and finally go off the disk, without that peculiar change of the umbra on one fide which is fo obvious on common occasions, notwithstanding it were an excavation whose nucleus or bottom is fo many miles below the level of the furface. In the four cales above stated, the distance of the remotest part of the nucleus from the fun's limb, when the vifual ray coming from it is just interrupted by the lip of the excavation, or in other words, the diflance of the nucleus from the limb when it was totally hid, was also computed. These distances are as follow;

16.93" Case III. Case I. - 4.70" - 2.70 - 8.90 IV. II. And it is remarkable, from the two last, how very near the limb a shallow spot of not more than 40" in diame-

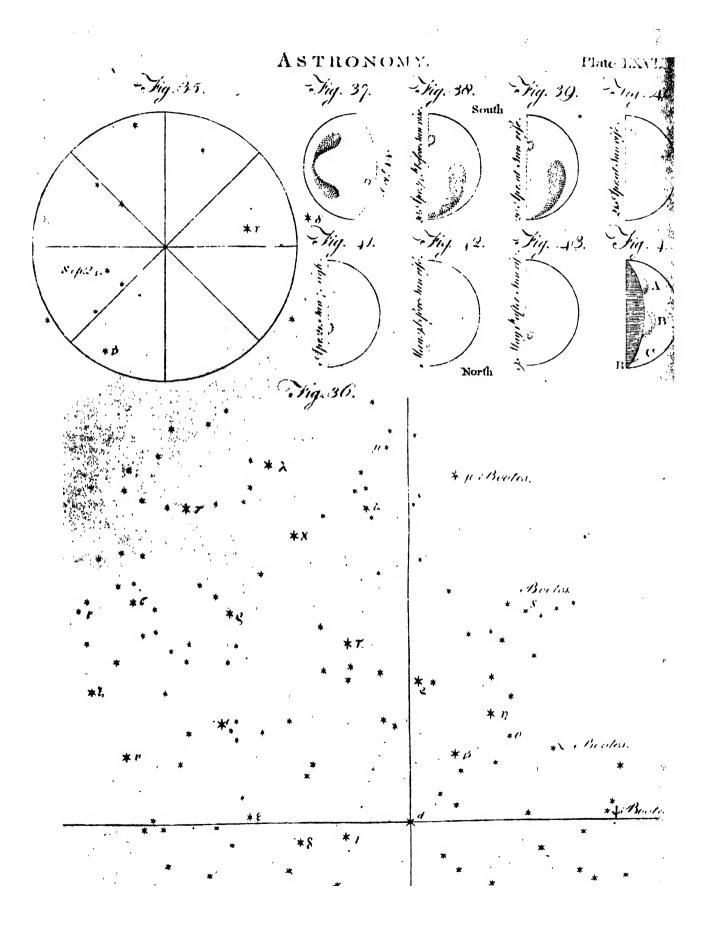

ter may come, before the nucleus wholly disappears."
After accribing the method in which these computations were made, the Doctor proceeds thus: "Perhaps it may be urged, that very shallow spots ought always to be known from the rest, and discover themfelves, by a furrounding umbra, very narrow, compared to the distribution of the nucleus; but we know far too dittle qualities of the luminous matter, and of of the nucleus; but we know far too The presimate causes of the spots, to say any thing at all upon a point of this kind. The breadth of the um-Conchions bra is, as assumed by the computations, about equal to from the that of the nucleus, though sometimes it varies more foreging or less; but how far these relative dimensions indicate ancel depth or shallowness, must be expounded only by obfervation, and not by any vague and imperfect notions of the nature and conflictation of the fun.

"The mention of a pit, or hollow or excavation feveral thousands of miles deep, reaching to that extent down through a luminous matter to darker regions, is ready to strike the imagination in a manner unfavourable to a just conception of the nature of the solar spots as now described. Upon first thoughts it may look strange how the fides and bottom of fuch vast abysses can remain fo very long in fight, whilft, by the fun's rotation, they are made to present themselves more and more obliquely to our view. But when it is confidered how extremely inconfiderable their greatest depth. is compared to the diameter of the fun, and how very wide and shelving they are, all difficulties of this fort will be entirely removed." Unless, however, we duly attend to these proportions, our notions upon the subject must be very erroneous; and it seems the more necessary to offer this caution, as this very thing is inaccurately represented in fig. 9. belonging to the Memoir under review, and in a way that may lead to miftakes. Instead of exhibiting a spot as depressed below the furface of the fun one hundreth part of his femidiameter, the fection of it is there determined by two lines drawn from the circumference, and meeting. in a point at the prodigious distance of one-fifth of the femidiameter below. Any reader, therefore, who. pleases, by turning to fig. 95. may see how very small a portion of the fun's body is made up of the luminous matter when supposed everywhere 3967 English. miles deep. A is a section of a spot 50" diameter, fitusted in the deepest part of this resplendent substance.

"What has now been infifted on at fo much length concerning the shallowness and more gradual shelving of fome few spote, will also apply to another objection which M. de la Lande views in a strong light.

" Here we find quoted the great spot in 1719, feen How a spotby M. Cassini; and, for the second time, that of June may appear-1703, feen by M. de la Hire; both which, on their to make an arrival at the limb, are faid to have made an indenta-indentation tion or dark notch in the disk; and this phenomenon on the fun's is mentioned as absolutely incompatible with spots being below the furface.

" It is most true, that if we look for any thing like this when the plane which coincides with the external boundary of the spots passes through the eye, the way that M. de la Lande confiders the matter, it must be very large indeed before the disk could be perceived deficient by any dark fegment. But may not a spot, even no larger than M. Cassini's, considered as an excavation, make, in a manner very different from this, fomething like a notch; for, by the way, this phenomenon is not in the Mem. Acad. nor anywhere else, that I know of, described with any fort of precision .--M. Cassini's great spot, by which we understood the nucleus, was of 30": and supposing the umbra equally broad, its diameter over all must have been 1, 30". It would therefore occupy an extent upon the fun's furface of 5° 22' fully. Now, suppose a circular space of that fize upon the fun diftinguished from the furround-

Conclusions ing lustre by such a failure of light as is peculiar to from the some spots, and suppose that it just touches the limb, foregoing it would full subtend an angle of more than 4". This being the case, might not a dusky shade, more or less remarkable according to the darkness of the umbra, commencing at the limb, and reaching inwards upon the disk, or in other words, a notch, be perceived ? Had M. Cassini's spot been a very shallow excavation, it appears by Case IV. that when viewed in this aspect, fome small part of the nucleus might have yet been visible; and might have contributed, along with the shade of the farthest umbra, and the still broader and deeper shade of the two ends of the umbra, to mark out the indentation.

> "Should it be faid, that these notches are always distinct and jet-black impressions on the disk, of an obvious breadth, and originating entirely from the opaque nucleus conceived as fomething prominent above the general furface, this can be shown inconsistent with fome circumstances we find accidentally mentioned in the case of M. de la Hire's spot; for of this great one it was faid, that when only 8" diftant from the limb, the nucleus was feen as a very narrow line. This was on June 3. 1703, at fix o'clock in the morning. Now, foralmuch as at that time its alleged elevation must have been to its apparent subtense very nearly as radius to coline of that arch of the fun's circumference whose versed sine was the 8" of distance from the limb, it is impossible that its breadth could been increased fentibly in its further progress towards the limb; and how any obvious black notch could be produced by the elevation contended for in this case is not conceivable.

> 4. I do not imagine, therefore, that the phenomena of notches in the disk, so inconsiderable and dubious as these seem to be, are by any means a proof of projecting nuclei, or that they are not reconcileable to fputs being depressions on the fun. A large shallow excavation, with the floping fides or umbra darker than the common, may, as has been shown, be more or less perceptible at the limb; and what perhaps is a farther confirmation of this, and feems to evince that fuch a concurrence of circumstances is necessary, is, that sometimes even large spots make no indentation. M. Cassini, in Mem. Acad. Tom. X. p. 581. describes the great spot of 1676, which he saw at its entrance with a telescope of 35 feet, as an obscure line parallel to the limb; but nowhere mentions that it made a notch-

> "Though we now and then see the surrounding umbra darker than at other times; yet when spots are deep, and the umbræ but little dusky, it is indeed impossible that we should see any thing of them, even though large, very near the limb: for here even the. nucleus, which lies buried, cannot in the least contribute to the effect, as it may do a little before its state. of evanelcence, when spots are very shallow. Accordingly, cases of this kind are perfectly agreeable to ex-

> "In reasoning concerning the nature of the spots, and particularly about the third dimension, the only. arguments which are admissible, and which carry with them a perfect conviction, are those grounded upon the principles of optical projection. If, for example, the far greater number of them be excavations some.

thousands of miles deep, certain changes of the umbra Conclusion would be observable when near the limb, as has been from the shown at fo much length. Were they very shallow, or Appearanquite superficial, both sides of the umbra would as to cen. fense contract alike in their progress toward the limb; for if, in Case IV. above stated, the spot had been supposed superficial, the apparent breadth of the side of the umbra next the centre of the disk would have made their only 1.62", and that of the fide opposite 1.27". Now, the whole of either of these quantities, and much more their difference, would be quite infenfible. Again, if the nucleus extended much above the common level, whilst the furrounding umbra was superficial, we should behold the manifest indications of this, by fuch an opaque body, when feen very obliquely, being projected across the farthest side of the umbra, and by hiding the whole or part of it before the time it would otherwife disappear. According to this or that condition of the spot, such things must infallibly obtain by the known laws of vision; and hence arguments refling upon fuch principles may be denominated optical ones. On the other hand, when spots are contemplated near the middle of the disk, a great variety of changes are observed in them, which depend not upon polition, but upon certain phylical causes producing real alterations in their form and dimensions. It is plain, that arguments derived from the confideration of such changes, and which, off that account, may be called physical arguments, can affist us but little in investigating their third dimensions; and, from the nature of the thing, must be liable to great uncertainty. The author of the Memoirs, in p. 511, &c. takes new ground, and proceeds with a number of objections depending upon that fort of reasoning which we have last defined. I must take notice, that a certain distinction has been here overlooked, which in my paper I have endeavoured to point out. Prefuming upon our great ignorance of many things which doubtlefs affect deeply the constitution of that wonderful body the sun, I offered in Part II. an account of the production, charges, and decay, of the fpots, confidered as excavations, in the most loose and problematical manner; stating every thing on this head in the form of queries .-Hence I would remark, that whatever inconfiftencies are imagined in the account I have delivered Part II. though such may be justly chargeable on certain principles there assumed, yet they ought not to be stated as prefumptions against the spots being really excavations or depressions in the luminous matter of the fun. This opinion must rest entirely upon the evidence held. forth in the first part of the paper, whatever be the fate of the account laid down in the fecond. It does not enter there as an hypothesis, but as a matter of fact previously established by optical arguments; and from optical arguments alone can there arife even any just prefumptions against it.

"It remains now only to make a few firschures up-Remarks on on M. de la Lande's theory of the folar spots, humbly M. de la fubmitting them to the confideration of the reader. The Lande's import of it is, ' that the fpots as phenomena arise from the folar dark bodies like rocks, which by an alternate flux and spots. reflux of the liquid igneous matter of the fun, fometimes raife their heads above the general furface. That part of the opaque rock, which at any time thus stands above, gives the appearance of the nucleus, whilst those

Lppearan-

onclusions parts, which in each lie only a little under the igneous from the matter, appear to us as the furrounding umbra."

" In the first place it may be remarked, that the whole proceeds upon mere supposition. This indeed the author himfelf very readily acknowledges. Though therefore it could not be disputed by arguments derived from observation, yet conjecture of any kind, if equally plaufible, might fitly be employed to fet afide its credit. Without entering into any tedious difcuffion, however, we shall confine ourselves to such particulars as appertain to the more obvious characters of the spots, and which also seem to be irreconcilable with the theory; and first of all with regard to the di-

flinguishing features of the umbra.

"M. Cassini, Mem. Acad. Tom. X. p. 582. Pl. VII. and M. de la Hire, Mem. Acad. 1703, p. 16. and I may add all other observers, and all good representations of the spots, bear testimony to the exterior boundary of the umbra being always well defined, and to the umbra itself being less and less shady the nearer it comes to the nucleus. Now it may be asked, how this could possibly be, according to M. de la Lande's theory? If the umbra be occasioned by our seeing parts of the opaque rock which lie a little under the furface of the igneous matter, should it not always be darkest next the nucleus? and, from the nucleus outward, should it not wax more and more bright, and at last lose itself in the general luftre of the fun's furface, and not terminate all at once in the darkest shade, as in fact it does? These few incongruities, which meet as it were in the very threshold of the theory, are so very palpable, that of themselves they raise insurmountable doubts. For, generally speaking, the umbra immediately contiguous to the nucleus, instead of being very dark, as it ought to be, from our feeing the immerfed parts of the opaque rock through a thin stratum of the igneous matter, is on the contrary very nearly of the same fplendour as the external furface.

" Concerning the nucleus, or that part of the opaque rock which stands above the surface of the sun, M. de la Lande produces no optical arguments in support of this third dimension or height. Neither does he say any thing particular as to the degree of elevation above the furface. But from what has been already hinted in the course of this paper, it appears, that if this were any thing fenfible, it ought to be discovered by phenomena very opposite to those which we have

found to be so general.

Again, a flux and reflux of the igneous matter, so confiderable as fometimes to produce a great number of fpots all over the middle zone, might affect the apparent diameter of the fun, making that which passes through his equator less than the polar one, by the retreat of the igneous matter towards those regions where no spots ever appear. But as a difference of this kind, of nearly one thousandth part of the whole, would be perceivable, as we learn from M. de la Lande's own observations, compared with those of Mr Short in Hifloire Acad. 1760, p. 123. it would feem, that the theory had this difficulty also to combat. Further: when among spots very near one another some are obferred to be increasing whilst others are diminishing, how is it possible this can be the effect of such a supposed Mux and reflux? This last inconsistency is menby the author himself, who endeavours to avoid it by making a new demand upon the general fund of Conclusions hypothesis, deriving from thence such qualities of the from the igneous matter as the case seems to require; and such surgoing appearantial be the method of proceeding in all systems macrely theoretical. But it is unnecessary to pursue at more length illufive speculations of this kind, especially as we lie under a conviction founded on fact, of the theory being utterly erroneous. It hardly differs in any respect from that proposed by M. de la Hire, and a little amended by the writer of the Histoire de l'Academie for 1707, p. 111. Views very much of the fame kind were even entertained by some so long ago as the days of Scheiner, as we find mentioned by that indefatigable author in his Rosa Ursina, p. 746."

2. Concerning the moon, it is allowed on all hands, Great inethat there are prodigious inequalities on her furface. qualities on This is proved by looking at her through a telescope, the surface at any other time than when she is full; for then there moon, is no regular line bounding light and darkness: but the confines of these parts appear as it were toothed and cut with innumerable notches and breaks; and even in the dark part, near the borders of the lucid furface, there are feen fome fmall spaces enlightened by the Sun's beams. Upon the fourth day after new moon, there may be perocived some shining points like rocks or small islands within the dark body of the moon; but not far from the confines of light and darkness there are observed other little spaces which join to the enlightened furface, but run out into the dark fide, which by degrees change their figure, till at last they come wholly within the illuminated face, and have no durk parts round them at all. Afterwards many more thing ing spaces are observed to arise by degrees, and to the pear within the dark fide of the moon, which belone they drew near to the confines of light and darkness were invitible, being without any light, and totally the merfed in the shadow. The contrary is observed in the decreasing phases, where the lucid spaces which joined the illuminated furface by degrees recede from it, and, after they are quite separated from the confines of light and darkness, remain for some time vilible, till at last they also disappear. Now it is impossible that this should be the case, unless these shining points were higher than the rest of the furface, so that the light of the fun may reach them.

Not content with perceiving the bare existence of Method of thefe lunar mountains, aftronomers have endeavoured measuring to measure their height in the following manner: Let the lunar EGD be the hemisphere of the moon illuminated by nountains, the fun, ECD the diameter of the circle bounding light and darkness, and A the top of a hill within the dark part when it first begins to be illuminated. Observe, With a telescope, the proportion of the right line AE, or the distance of the point A from the lucid surface to the diameter of the moon ED; and because in this cafe the ray of light ES touches the globe of the moon, AEC will be a right angle by 16th Prop. of Euclid's third book; and therefore in the triangle AEC having the two fides AE and EC, we can find out the third fide AC; from which subducting BC or EC, there will remain AB the height of the mountain. ciolus affirms, that upon the fourth day after new moon he has observed the top of the hill called St Catherine's to be illuminated, and that it was diftant from the confines of the lucid furface about a fixteenth part

Conclusions of the moon's diameter. Therefore, if CE=8, AE

from the will be 1, and AC'=CE'+AE' by Prop. 47. of Enforegoing chid's first book. Now, the square of CE being 64, and the square of AE being 1, the square of AC will be 65, whose square root is 8,062, which expresses the length of AC. From which deducting BC=8, there will remain AB=0,062. So that CB or CE is therefore to AB as 8 is to 0,062, that is, as 8000 is to 62. If the diameter of the moon therefore was known, the height of this mountain would also be known. This demonitration is taken from Dr Keill, who supposes the femidiameter of the moon to be 1182 miles; according to which, the mountain mult be somewhat more than nine miles of perpendicular height; but alteonomers having now determined the moun's femidiameter to be only 1000 miles, the beight of the mountain will be nearly 81 miles.

112 Height of the lunar prountains overrated.

M: Herfchel s ob. fervations on them.

In the former edition of this work, we could not help making some remarks on the improbability that the mountains of the moon, a planet so much inferior in fize to the earth, foodld exceed in fuch vast proportion the highest of our mountains, which are computed at little more than one-third of the height just mentioned. Our remark is now confirmed by the observations of Mr Herschel. After explaining the method used by Galdeo, Hevelius, &c. for measuring the lunar mountains, he tells us, that the former takes the distance of the top of a lunar mountain from the line that divides the illuminated part of the disk from that which is in the shede to be equal to one-twentieth of the moon's diameter; but Heuelius makes it only one twenty-fixth. When we calculate the height of fuch a mountain, therefore, it will be found, according to Galileo, almost 54 miles; and according to Hevelius st miles, admitting the moon's diameter to be 2180 Mr Fergulon, however, fays (Altronomy Explained, \$ 252.), that some of her mountains, by comparing their height with their diameter, are found to be three times higher than the highest hills on earth: and Keill, in his Aftronomical Lectures, has calculated the height of St Catherine's hill, according to the obfervations of Racciolus, and finds it nine miles. Having promifed these accounts, Mr Herschel explains his method of taking the height of a lunar mountain from observations made when the moon was not in her quadratuse, as the method laid down by Hevelius anfwere only to that particular case; for in all others the projection must appear shorter than it really is. "Let SLM, fays he, or s lm, (fig. 96.) be a line drawn from the fun to the mountain, touching the moon at L or 4 and the mountain at M or m. Then, to an observer at E or c, the lines LM, Im, will not appear of the some length, though the mountain should be of an equal height; for LM will be projected into on, and I'm into ON. But these are the quantities that are taken by the micrometer when we observe a mountain to project from the line of illumination. From the observed quantity on, when the moon is not in her quadrature, to find LM, we have the following analogy. The triangles o OL, r ML, are fimilar; therefore Lo: LO: Lr: LM, or $\frac{LO \times n \pi}{Lo}$ = LM: but

LO is the radius of the moon, and Lroron is the observed distance of the mountain's projection; and Lo is the fine of the angle ROL = o LS; which we may take to be the dillance of the fun from the moon Conclusion without any material error, and which therefore we may from the find at any given time from an ephemeris.

"The telescope used in these observations was a Newtonian reflector of fix fect eight inches focal length, to which a micrometer was adapted, confifting of two parallel hairs, one of which was moveable by means of a line forew. The value of the parts shown by the index was determined by a trigonometrical observation of a known object at a known diffance, and was verified by feveral trials. The power was always 222, excepting where another is expressly mentioned; and this was also determined by experiment, which frequently differs from theory on account of fome small errors in the data, hardly to be avoided. The moon having sufficient light, an aperture of no more than four inches was made use of; and, says Mr Herschel, "I believe, that for distinctness of vision, this instrument is perhaps equal to any that ever was made."

With this instrument he observed a prominence, which he calls a rock, fituated near the Lacus Niger of Hevelius, and found that it projected 41.56". reduce this into miles, put R for the semidiameter of the moon in seconds, as given by the nautical almanack at the time of observation, and Q for the observed quantity, also in seconds and centelimals; then it will be in general, R: 1090:: Q: 1090 Q = on in miles.

Thus it is found, that 41.56" is 46.79 miles. The distance of the sun from the moon at that time was, by the nautical almanack, about 93° 577; the fine of.

which to the radius 1 is .9985, &c. and $\frac{o n}{Lo}$ in this cafe is LM =46.85 miles. Then, by Hevelius's method, the perpendicular height of the rock is found to be about one mile. At the fame time, a great many rocks, fituated about the middle of the disk, projected from 25.92" to 26.56"; which gives on about 29.3 miles: fo that these rocks are all less than half a mile high.

These observations were made on the 13th of November 1779. On the 13th of January 1780, examining the mountains of the moon, he found that there was not one of them fairly placed on level ground, which is very necessary for an exact measurement of the projection: for if there should be a declivity on the moon before the mountains, or a tract of hills placed fo as to call a shadow upon that part before them which would otherwise be illuminated, the projection would appear too large; and, on the contrary, should there be a rifing ground before them, it would appear too little.

Proceeding in this cautious manner, Mr Herschel measured the height of many of the lunar prominences, and draws at last the following conclusions:-" From these observations I believe it is evident, that the height of the lunar mountains in general is greatly overrated; and that, when we have excepted a few, the generality do not exceed half a mile in their perpendicular elevation. It is not fo eafy to find any certain mountain exactly in the fame fituation it has been measured in before: therefore some little difference must be expected in these measures. Hitherto I have not had an opportunity of particularly observing the three mountains mentioned by Hevelius; nor that

lollond's

ilescopes.

from the the moon's diameter. If Keill had calculated the foregoing height of this last mentioned hill according to the ances. theorem I have given, he would have found (supposing the observation to have been made, as he says, on the fourth day after new moon) that its perpendicular height could not well be less than between 11 and 12 miles. I shall not fail to take the first opportunity of observing these four, and every other mountain of any eminence; and if other persons, who are furnished with good telescopes and micrometers, would take the quantity of the projection of the lunar mountains, I make no doubt but that we should be nearly as well acquainted with their beights as we are with the elelation to vation of our own. One caution I would beg leave to cohferved mention to those who may use the excellent 31 feet refractors of Mr Dolland. The admirable quantity of light, which on most occasions is so defirable, will probably give the measure of the projection somewhat larger than the true, if not guarded against by proper limitations placed before the object glass. I have taken no notice of any allowance to be made for the refraction: a ray of light must suffer in passing through the atmosphere of the moon, when it illuminates the top of the mountain, whereby its apparent height will be leffened, as we are too little acquainted with that atmo-Sphere to take it into consideration. It is also to be obferved, that this would equally affect the conclusions of Hevelius, and therefore the difference in our inferences would still remain the same."

In the continuation of his observations, Mr Herschel informs us that he had measured the height of one of the mountains which had been measured by Herelius. "Antitaurus (says he), the mountain measured by Hevelius, was badly situated; because Mount Moschus and its neighbouring hills cast a deep shadow, which may be mistaken for the natural convexity of the moon. A good, full, but just measure, 25.105"; in miles, 29.27: therefore LM 31.7 miles, and the perpendicular height not quite half a mile. As great exactness was desired in this observation, it was repeated with very nearly the same result. Several other mountains were measured by the same method; and all his observations concurred in making the height of the lunar mountains much less than what former astronomers had done. Mount Lipulus was found to be near two-thirds of a mile; one of the Apennine mountains between Lacus Trasimenus and Pontus Euxinus measured a mile and a quarter; Mons Armenia, near Taurus, two-thirds of a mile; Mons Leucoptera, three quarters of a mile. Mons Sacer projected 45.625"; 'but (fays he) I am almost certain that there are two very confiderable cavities or places where the ground descends below the level of the convexity, just before these mountains; so that these measures must of course be a good deal too large: but supposing them to be just, it follows, that on is 50.193 miles, I.M=64 miles, and the perpendicular height above

As moon has on its surface mountains and valleys in common with the earth, some modern astronomers have discovered a still greater similarity, viz. that some of these are really volcanoes, emitting fire as those on earth do. An appearance of this kind was discowered some years ago by Don Ulloa in an eclipse of

the fun. It was a small bright spot like a star near Conclusions the margin of the moon, and which he at that time from the supposed to have been a hole with the fun's light shin- foregoing ing through it. Succeeding observations, however, ances. have induced astronomers to attribute appearances of this kind to the eruption of volcanic fire; and Mr Herschel has particularly observed several eruptions of the lunar volcanoes, the last of which he gives an account of in the Phil. Trans. for 1787. "April 19. 10h. 36' sidereal time. I perceive (says he) three volcanoes in different places of the dark part of the Two of them are either already nearly extinct, or otherwise in a flate of going to break out; which perhaps may be decided next lunation. The third shows an actual eruption of fire or luminous matter. I measured the distance of the crater from the northern limb of the moon, and found it 3' 57.3"; its light is much brighter than the nucleus of the comet which M. Mechain discovered at Paris the 10th of this month.

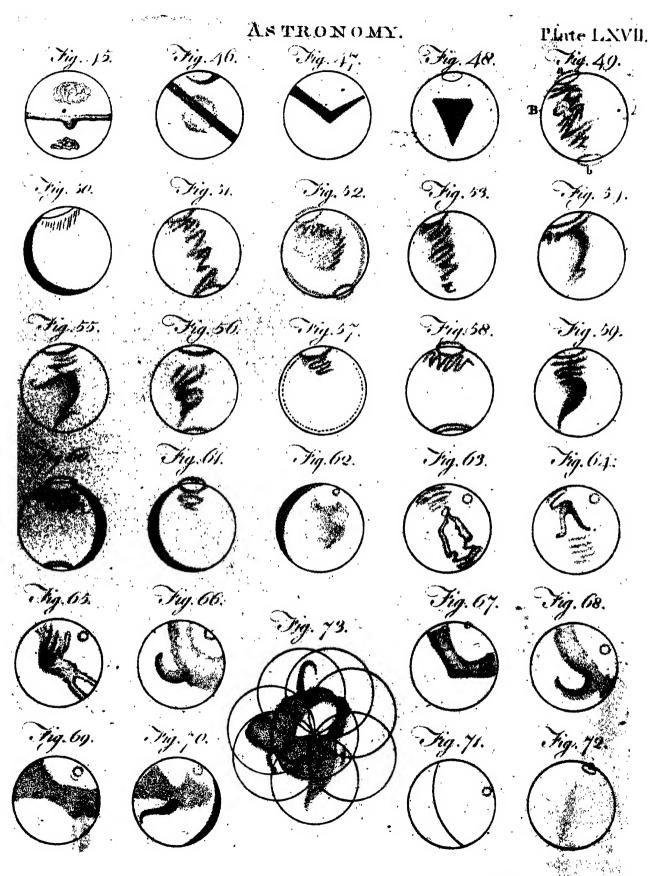

" April 20. 10h. 2' sidereal time. The volcano burns with greater violence than last night. Its diameter cannot be less than 3", by comparing it with that of the Georgian planet: as Jupiter was near at hand, I turned the telescope to his third satellite, and estimated the diameter of the burning part of the volcano to be equal to at least twice that of the satellite; whence we may compute that the shining or burning matter must be above three miles in diameter. It is of an irregular round figure, and very sharply defined on the edges. The other two volcanoes are much farther towards the centre of the moon, and refemble large, pretty faint nebule, that are gradually much brighter in the middle; but no well defined luminous spot can be discerned in them. These three spots are plainly to be diftinguished from the rest of the marks upon the moon; for the reflection of the fun's rays from the earth is, in its present situation, sufficiently bright, with a ten feet reflector, to show the moon's spots, even the darkest of them; nor did I perceive any fimilar phenomena last lunation, though I then viewed the same places with the same instrument.

" The appearance of what I have called the adual fire, or eruption of a volcano, exactly refembled a fmall piece of burning charcoal when it is covered by a very thin coat of white ashes, which frequently adhere to it when it has been some time ignited; and it had a degree of brightness about as strong as that with which such a coal would be seen to glow in faint daylight. All the adjacent parts of the volcanic mountain feemed to be faintly illuminated by the eruption, and were gradually more obscure as they lay at a greater distance from the crater. This eruption refembled much that which I saw on the 4th of May in the year 1783, but differed confiderably in magnitude and brightness; for the volcano of the year 1783, though much brighter than that which is now burning, was not nearly so large in the dimensions of its eruption: the former seen in the telescope resembled a star of the fourth magnitude as it appears to the naked eye; this, on the contrary, shows a visible disk of luminous matter very different from the sparkling brightness of star light."

Concerning the nature of the moon's substance there Conjectures have been many conjectures formed. Some have ima-her sub-

145 Volcanoes difcovered in the word.

gined, flance.

Appearan-

Conclusions gined, that, besides the light reflected from the sun, from the the moon hath also some obscure light of her own, by foregoing which she would be visible without being illuminated by the funbeams. In proof of this it is urged, that during the time of even total eclipses the moon is still visible, appearing of a dull red colour, as if obscured by a great deal of smoke. In reply to this it hath been advanced, that this is not always the case; the moon fometimes disappearing totally in the time of an eclipse, so as not to be discernible by the best glasfes, while little stars of the fifth and fixth magnitudes were distinctly seen as usual. This phenomenon was observed by Kepler twice, in the years 1580 and 1583; and by Hevelius in 1620. Ricciolus and other Ie-Juits at Bologna, and many people throughout Holland, observed the same on April 14. 1642: yet at Venice and Vienna she was all the time conspicuous. In the year 1703, Dec. 23. there was another total obscuration. At Arles, the appeared of a yellowish brown; at Avignon, ruddy and transparent, as if the fun had shone through her; at Marseilles, one part was reddish and the other very dusky; and at length, though in a clear sky, she totally disappeared. The general reason for her appearance at all during the time of ecliples shall be given afterwards: but as for these particular phenomena, they have not yet, as far as we know, been satisfactorily accounted for.

Different conjectures have also been formed concerning the fpots on the moon's furface. Some philosophers have been to taken with the beauty of the brightest places observed in her disk, that they have imagined them to be rocks of diamonds; and others have compared them to pearls and precious stones. Dr Keill and the greatest part of astronomers now are of opinion, that these are only the tops of mountains, which by reason of their elevation are more capable of reflecting the fun's light than others which are lower. The duskthe speth, he says, cannot be seas, nor any thing of a liquid substance; because, when examined by the telefcontineller appear to confift of an infinity of caverne and ty pits, whole shadows fall within them, which can never be the case with seas, or any liquid substance: but, even within these spots, brighter places are also to be observed; which, according to his hypothesis, ought to be the points of rocks flanding up within the cavities. Dr Long, however, is of opinion, that feveral of the dark spots on the moon are really water, May not the lunar feas and lakes (fays he) have iflands in them, wherein there may be pits and caverns? And if some of these dark parts be brighter than others, may not that be owing to the feas and lakes being of different depths, and to their having rocks in some

places and flats in others?

Vol. II. Part II.

It has also been urged, that if all the dark spots obferved on the moon's furface were really the shadows of mountains, or of the fides of deep pits, they could not possibly be so permanent as they are found to be; but would vary according to the position of the moon with regard to the fun, as we find shadows on earth are varied according as the earth is turned towards or from the fun. Accordingly it is pretended, that variable spots are actually discovered on the moon's disk, and that the direction of these is always opposite to the fun. Hence they are found among those parts which are foonest illuminated in the increasing moon, and in

the decreasing moon lose their light sooner than the in- Conclusions termediate ones; running round, and appearing some. from the times longer, and sometimes shorter. The permanent Appear is dark spots, therefore, it is said, must be some matter ces. which is not fitted for reflecting the rays of the fun fo much as the bright parts do: and this property, we know by experience, belongs to water rather than land; whence these philosophers conclude, that the moon, as well as our earth, is made up of land and fcas,

It has been a matter of dispute whether the moon Whether has any atmosphere or not. The following arguments the moon has any at-

have been urged by those who take the negative side. has my atmosphere.

1. The moon constantly appears with the same brightness when there are no clouds in our atmosphere; which could not be the case if she were surrounded with an atmosphere like ours, so variable in it density, and fo frequently obscured by clouds and vapours. 2. In an appulse of the moon to a star, when she comes so near it that part of her atmosphere is interposed between our eye and the star, refraction would cause the latter to feem to change its place, fo that the moon would appear to touch it later than by her own motion she would do. 3. Some philosophers are of opinion, that because there are no seas or lakes in the moon, there is therefore no atmosphere, as there is no water to be

raifed up in vapours.

All these arguments, however, have been answered by other aftronomers in the following manner: 1. It is denied that the moon appears always with the fame brightness, even when our atmosphere appears equally clear. Hevelius relates, that he has several times found in skies perfectly clear, when even stars of the fixth and feventh magnitude were visible, that at the same altitude of the moon, and the same elongation from the earth, and with one and the same telescope, the moon and its maculæ do not appear equally lucid, clear, and conspicuous at all times; but are much brighter and more distinct at some times than at others. From the circumstances of this observation, say they, it is evident that the reason of this phenomenon is neither in our air, in the tube, in the moon, nor in the spectator's eye; but must be looked for in something existing about the moon. An additional argument is drawn from the different appearances of the moon already mentioned in total eclipses, which are supposed to be owing to the different conflictations of the lunar atmosphere.

To the second argument, Dr Long replies, that Sir Isaac Newton has shown (Princip. Prop. 97. cor. 5.), that the weight of any body upon the moon is but a third part of what the weight of the same would be upon the earth: Now the expansion of the air is reci- why the procally as the weight which compresses it : the air, light is not therefore, furrounding the moon, being pressed toge-retracted by ther by a weight, or being attracted towards the centre the moon's of the moon by a force equal only to one-third of that atmosphere. which attracts our air towards the centre of the earth, it thence follows, that the lunar atmosphere is only one third as dense as that of the earth, which is too little to produce any sensible refraction of the stars light. Other aftronomers have contended that such refraction was fometimes very apparent. M. Cassiai fays that he frequently observed Saturn, Jupiter, and the fixed stars, to have their circular figure changed into an elliptical one, when they approached either to the moon's dark or illuminated limb; though they

3 M

Appearan-

Conclusions own, that in other occultations no such change could from the be observed. With regard to the fixed stars, indeed, foregoing it has been urged, that, granting the moon to have an atmosphere of the same nature and quantity as ours, one fuch effect as a gradual diminution of light ought to take place; at least, that we could by no means be capable of perceiving it. Our atmosphere is found to be so rare at the height of 44 miles as to be incapable of refracting the rays of light. This height is the 180th part of the earth's diameter; but fince clouds are never observed higher than four miles, we must conclude that the vaporous or obscure part is only one 1980th. The mean apparent diameter of the moon is 31' 29", or 1889 feconds: therefore the obscure parts of her atmosphere, when viewed from the earth, must subtend an angle of less than one second; which space is passed over by the moon in less than two seconds of time. It can therefore hardly be expected that observation should generally determine whether the

supposed obscuration takes place or not.

The third argument is necessarily inconclusive, because we know not whether there is any water in the moon or not; nor, though this could be demonstrated, would it follow that the lunar atmosphere answers no other purpose than the raising of water into vapour. Luninous There is, however, a strong argument in favour of appearance of a luminous ring round the moon in the time of folar eclipses. In the eclipse of May 1, 1706, Captain Stanyan, from Bern in Switzerland, writes, that " the fun was totally darkened there for the space of four minutes and a half: that a fixed star and planet appeared very bright: that his getting out of the eclipse was preceded by a blood-red streak of light from his left limb, which continued not longer than fix or seven seconds of time; then part of the sun's disk appeared, all on a sudden, brighter than Venus was ever feen in the night; and in that very instant gave light and shadow to things as strong as moon-light uses to do." The publisher of this account observes, that the red streak of light preceding the emersion of the fun's body, is a proof that the moon has an atmofphere; and its short continuance of five or fix seconds shows that its height is not more than the five or fix hundredth part of her diameter.

Fatio, who observed the same eclipse at Geneva, tell us, that " there was feen during the whole time of the total immersion, a whiteness which seemed to break out from behind the moon, and to encompass her on all fides equally: this whiteness was not well defined on its outward fide, and the breadth of it was not a twelfth part of the diameter of the moon. The planet appeared very black, and her disk very well defined within the whiteness which encompassed it about, and was of the fame colour as that of a white crown or halo of about four or five degrees in diameter, which accompanied it, and had the moon for its centre. A little after the fun had begun to appear again, the whiteness, and the crown which had encompassed the moon, de entirely vanish." "I must add (says Dr Long), that this description is a little perplexed, either through the fault of the author or of the translator; for Lauppole Fatio wrote in French: however, it plainly pears by it that the moon's atmosphere was visible, furrounded by a light of larger extent, which

I think must be that luminous appearance (the zodiacal Concussions light) mentioned from Cassini." Flamstead, who pub- from the lished this account, takes notice, that, according to here observations, the altitude of the moon's atmo-Sphere cannot be well supposed less than 130 geographical miles; and that probably this atmosphere was never discovered before this eclipse, by reason of the finallness of the refraction, and the want of proper obfervations.

An account of the fame eclipse, as it appeared at Zurich, is given by Dr Scheuchzer, in the following words: We had an ecliple of the fun, which was both total and annular; total, because the whole sun was covered by the moon; annular, not what is properly so called, but by refraction: for there appeared round the moon a bright shining, which was owing to the rays of the fun refracted through the atmosphere of the moon.

Dom. Cassini, from a number of accounts sent him from different parts, fays, that in all those places where it was total, during the time of total darkness, there was feen round the moon a crown or broad circle of pale light, the breadth whereof was about a 12th part of the moon's diameter: that at Montpelier, where the observers were particularly attentive to see if they could diflinguish the zodiacal light already mentioned, they took notice of a paler light of a larger extent, which furrounded the crown of light before mentioned, and spread itself on each side of it, to the distance of four degrees. He then mentions Kepler's opinion, that the crown of light which appears round the moon during the total darkness in an eclipse of the sun is caufed by some celestial matter surrounding the moon, of fufficient density to receive the rays of the fun and fend them to us; and that the moon may have an atmosphere fimilar to that of our earth, which may refract the fun's light.

A total eclipse of the sun was observed on the 22d Dr Halley of April O. S. in the year 1715, by Dr Halley at Lon-account of don, and by M. Louville of the Academy of Sciences s folar at Paris. Dr Halley relates, that "when the first art of eclipse art of ecliple in the fun remained on his east fide, it grew very faint, and 1715. was cafily supportable to the naked eye even through the telescope, for above a minute of time before the total darkness; whereas, on the contrary, the eye could not endure the fplendour of the emerging beams through the telescope even from the first moment. To this, two causes perhaps concurred: the one, that the pupil of the eye did necessarily dilate itself during the darkness, which before had been much contracted by looking on the fun: the other, that the eastern parts of the moon, having been heated with a day near as long as 30 of ours, must of necessity have that part of its atmosphere replete with vapours raised by the so long continued action of the fun; and, by confequence, it was more dense near the moon's surface, and more capable of obstructing the sun's beams; whereas at the same time the western edge of the moon had suffered as long a night, during which there might fall in dews all the vapours that were raifed in the preceding long day; and for that reason, that that part of its atmosphere might be seen much more pure and transparent.

"About two minutes before the total immersion, the remaining part of the fun was reduced to a very fine horn, whose extremities seemed to lose their acute-

149 ved about the moon in total relipica

Conclusions nefs, and to become round like stars; and for the from the space of about a quarter of a minute a small piece of foregoing the fouthern horn of the eclipse seemed to be cut off from the rest by a good interval, and appeared like an

oblong star rounded at both ends; which appearance would proceed from no other cause but the inequalities of the moon's furface; there being some elevated parts thereof near the moon's fouthern pole, by whose interposition part of that exceedingly fine filament of light was intercepted. A few feconds before the fun was totally hid, there discovered itself round the moon a luminous ring, about a digit, or perhaps a tenth part of the moon's diameter in breadth. It was of a pale whiteness, or rather of a pearl colour, scenning to me a little tinged with the colour of the iris, and to be concentric with the moon; whence I concluded it the moon's atmosphere. But the great height of it, far exceeding that of our earth's atmosphere, and the observations of some who found the breadth of the ring to increase on the west side of the moon as the emersion approached, together with the contrary fentiments of those whose judgments I shall always revere, make me less consident, especially in a matter to which I gave

not all the attention requisite.

"Whatever it was, this ring appeared much brighter and whiter near the body of the moon than at a distance from it; and its outward circumference, which was ill defined, seemed terminated only by the extreme rarity of the matter of which it was composed, and in all respects resembled the appearance of an enlightened atmosphere form from far . hut whether is beleased ... the fan or moon, I shall not pretend to determine. thus of During the whole time of the total eclipse, I kept my light appear telescope constantly fixed on the moon, in order to obto derefrom ferve what might occur in this uncommon appearance; hehind the and I faw perpetual flashes or corufcations of light, which Icemed for a moment to dart out from behind the moon, now here, now there, on all fides, but more especially on the western side, a little before the emerfion; and about two or three seconds before it, on the same western side, where the sun was just coming out, a long and very narrow streak of dusky but strong red light feemed to colour the dark edge of the moon, though nothing like it had been feen immediately after the emersion. But this instantly vanished after the appearance of the fun, as did also the aforesaid luminous ring."

152 Mr Lou-Ville's olr-

Mr Louville relates, that a luminous ring of a filver colour appeared round the moon as foon as the fun was entirely covered by her disk, and disappeared the moment he recovered his light; that this ring was brightest near the moon, and grew gradually fainter towards its outer circumference, where it was, however, defined; that it was not equally bright all over, but had feveral breaks in it: but he makes no doubt of its being occasioned by the moon's atmosphere, and thinks that the breaks in it were occasioned by the mountains of the moon: he fays also, that this ring had the moon, and not the fun, for its centre, during the whole time of its appearance. Another proof brought by him of the moon having an atmosphere is, that, towards the end of the total darkness, there was seen on the fide of the moon on which the fun was going to appear, a piece of a circle, of a lively red, which might be owing to the red rays that are least refrangible be-

ing transmitted through the moon's atmosphere in the Conclusions greatest quantity; and that he might be affored this from the redness did not proceed from the glasses of his tele-Appearan-scope, he took care to bring the red part into the ces.

middle of his glasses.

He lays great stress on the streaks of light which he faw dart inflantaneously from different places of the Lightning moon during the time of total darkness, but chiefly supposed to near the eastern edge of the disk; these he takes to be in the lightning, such as a spectator would see flashing from moon. the dark hemisphere of the earth, if he were placed upon the moon, and faw the earth come between himfelf and the fun. " Now (fays Dr Long) it is highly probable, that if a man had, at any time, a view of that half of the earth when it is night, he would fee lightning in some part of it or other." Louville farther observes, that the most mountainous countries are most liable to tempelts; and that mountains being more frequent in the moon, and higher than on earth *, thun- 'See No der and lightning must be more frequent there than 142, er feqwith us; and that the eastern side of the moon would be most subject to thunder and lightning, those parts having been heated by the fun for half the month immediately preceding. It must have be observed, that Halley, in mentioning these slathes, says they seemed to come from behind the moon; and Louville, though he fays they came fometimes from one part and fome-times from another, owns, that he himself only law them near the eastern part of the disk; and that, not knowing at that time what it was that he raw, he did not take notice whath a the fame appearance was to be seen on other parts of the moon or not. He tells us, however, of an English altronomer, who presented the Royal Society with a draught of what he faw in the moon at the time of this relipfe; from which Louville feems to conclude that lightnings had been obferved by that astronomer near the centre of the moon's disk. " Now (fays Dr Long) thunder and lightning would be a demonstration of the moon having an atmosphere similar to ours, wherein vapours and exhalations may be supported, and furnish materials for clouds, florms, and tempells. But the flrongest proof brought by Louville of the moon having an atmosphere is this, that as foon as the ecliple began, those parts of the fun which were going to be hid by the moon grew fenfibly palish as the former came near them, suffering beforehand a kind of imperfect celipfe or diminution of light; this could be owing to nothing elfe but the atmosphere of the moon, the castern part whereof going before her reached the fun before the moon did. As to the great height of the lunar atmosphere Great which from the breadth of the luminous ring being the lunar about a whole digit would upon a calculation come out atmosphere 180 miles, above three times as high as the atmosphere accounted of the earth, Louville, thinks that no objection; fince for. if the moon were furrounded with an atmosphere of the fame nature with that which encompasses the earth. the gravitation thereof towards the moon would be but one third of that of our atmosphere towards the earth; and confequently its expansion would make the height of it three times as great from the moon as is the height of our atmosphere from the earth."

The fame luminous ring has been observed in other total eclipses, and even in such as are annular, though without the luminous streaks or stastes of lightning

3 M 2 above Conclusions above-mentioned; it is even taken notice of by Plutarch:

from the however, some members of the academy at Paris have foregoing Appearanout having recourse to a lunar atmosphere; and for this purpose they made the following experiments: The image of the fun coming through a fmall hole into a These phe-darkened room, was received upon a circle of wood or nomena o- metal of a diameter a good deal larger than that of the therwifeac- fun's image; then the shadow of this opaque circle was sounted for east upon white paper, and there appeared round it, on the paper a luminous circle fuch as that which furrounds the moon. The like experiment being made with a globe of wood, and with another of stone not polished, the shadows of both these cast upon paper were surrounded with a palish light, most vivid near the shadows, and gradually more diluted at a diffance from them. They observe also, that the ring round the moon was feen in the eclipse of 1706 by Wurzelbaur, who cast her shadow upon white paper. The same appearance was observed on holding an opaque globe in the fun, fo as to cover his whole body from the eye; for, looking at it through a fmoked glass, in order to prevent the eye from being hurt by the glare of light it would otherwife be exposed to, the globe appeared fur-

> in a total eclipse of the fun. Thus they folve the phenomenon of the ring feen round the moon by the inflection, or diffraction as they call it. of the folar rays, passing nearan opaque substance. As for the imall itreaks of light above-mentioned, and which are supposed to ne ughtang, the properties along by an hypothesis concerning the cavities of the moon themselves; which they consider as concave mirrors reflecting the light of the fun nearly to the same point; and as these are continually changing their situation with great velocity by the moon's motion from the fun. the light which any one of them fends to our eye is feen but for a moment. This, however, will not account for the flather, if any fuch there are, feen near the centre of the disk, though it does, in no very fatisfactory manner, account for those at the edges.

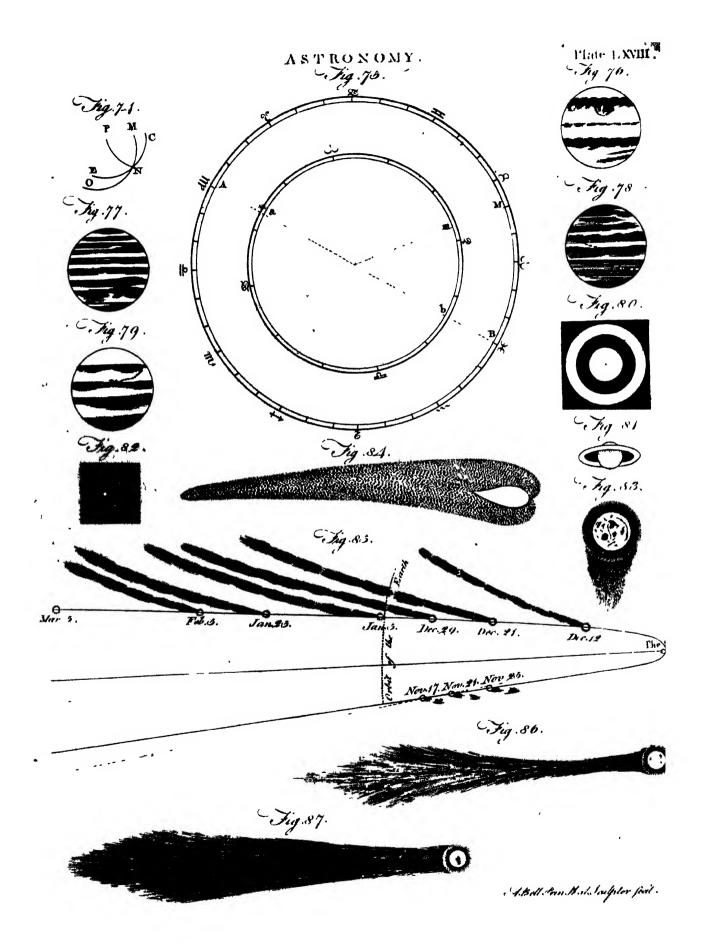

rounded with a light refembling that round the moon

7.56 De uleaixed flars by the MOUTI.

It has already been observed, that the occultations consofthe of the fixed stars and planets by the moon, in general happen without any kind of refraction of their light by the lunar atmosphere. The contrary, however, has fometimes been observed, and the stars have been feen manifestly to change their shape and colour on going behind the moon's disk. An instance of this happened on the 28th of June N. S. in the year 1715, when an occultation of Venus by the moon happened in the day-time. Some aftronomers in France observing this with a telescope, saw Venus change colour for about a minute before the was hid by the moon; and the fame change of colour was observed immediately after her emersion from behind the disk. At both times the edge of the disk of Venus that was nearest the moon appeared reddift, and that which was most distant of a bluish colour. These appearances, however, which might have been taken for proofs of a lunar atmoiphere, were supposed to be owing to the observers having directed the axis of their telescopes towards the moon. This would necessarily cause any planet or star mear the edge of the moon's disk to be seen through those part of the glasses which are near their circum-Scrence, and consequently to appear coloured. This

was evidently the case, from other observations of an Conclusions occultation of Jupiter by the moon the fame year, from the when no fuch appearance of refraction could be perforegoing ceived while he was kept in the middle of the telescope. Miraldi allo informs us, that he had observed before this two other occultations of Venus and one of Jupiter; and was always attentive to fee whether those planets changed their figure or colour either upon the approach of the moon to cover them, or at their first coming again into fight; but never could perceive any fuch thing. Nor could he, in a great number of occultations of the fixed flars, perceive the finallest apparent change in any of them, excepting once that a fixed flar feemed to increase its diflance a little from the moon as it was going to be covered by her; but this, he suspected, might be owing to his telescope being directed so as to have the star feen too far from the middle of its aperture. He concludes, therefore, that the moon has no atmosphere: and he remarks, that at Montpelier, perhaps because the air is clearer there than at London, the luminous ring round the moon appeared much larger than at London; that it was very white near the moon, and gradually decreasing in brightness, formed round her a circular area of about eight degrees in diameter. If, fays he, this light was caused by the atmosphere of the moon, of what a prodigious extent must that atmosphere

Before we enter upon any further speculations con-Of plu-cerning the celestial bodies, we shall here take some raity of muche of the dudining of a plurality of worlds; to worlds. which we are naturally led by the question, Whether the moon is inhabited or not? This is a hypothetis of very ancient date, and which in modern times line been revived in fuch a manner as now to be almost adopted as an undoubted truth. Plutarch, Diogenes. Lacrtius, and Stobeus, inform üs, that this doctrine was embraced by several of the ancient Greek philosopheis; from which authors Gregory has given us extracts in the Preface to his Aftronomy. "Among the moderns (fays Dr Long), Huygens has written a treatife which he calls Cosmotheores, or A view of the world, worth perusing. One thing, however, I must find fault with; that, in peopling the planets with reafonable creatures, he infilts upon their being in all points exactly fimilar to the human race, as to the shape of their bodies and the endowments of their minds: this is too confined a thought; for we cannot but acknowledge that infinite Power and Wisdom is able to form rational beings of various kinds, not only in shape and figure different from the human, but endowed also with faculties and fenfes very different; fuch as in our prefent state we can have no idea of." With regard to the probability of the doctrine itself, the Doctor expresses himself in the following manner: " That the earth and all the creatures thereon were created to be subservient to the use of man, we may believe upon the authority of the facted writer, Pfalm viii. but that the flars and planets were formed only to befpangle the canopy of heaven with their glimmering, which does not furnish us with the twentieth part of the light the moon gives, I think it not at all probable: this is contrary to the observation made by the best philosophers. that nature is magnificent in all her defigns, but frugal in the execution of them. It is commonly faid, that

Conclusions nature does nothing in vain : now by Nature, in a from the found fenfe, must be understood the present order and foregoing disposition of things according to the will of the Supreme Being."

150 Objections to the poifibility of this doctruic.

160

Inconclu-

five.

Objections have been made to the possibility of this hypothesis from the different degrees of heat and light which the planets receive from the fun, according to their various distances from him. On Venus, for inflance, the heat must be more than double what it is with us, and on Mercury upwards of ten times as great; fo that were our earth brought as near the fun as Mercury, every drop of liquid would be evaporated into fleam, and every combustible folid fet on fire; while, on the other hand, were we removed to the diflance of the superior planets, such as the Georgium Sidus, Saturn, or even Jupiter, there is the highest probability that our liquids would all be congealed into ice, at the same time that the climate would be utterly insupportable by such creatures as we are. Objections of the same kind are drawn from the small quantity of light which falls upon the more diffant planets, which it is thought would be infufficient for the purposes of living and rational creatures. Such arguments as thefe, however, are by no means conclusive; for, as Dr Long justly observes, " we are sure, that if the all-wife fupreme Being hath placed animals on the planets, he has fitted the inhabitants to the places, and the places to the inhabitants." We shall therefore only add the fol-† Introd. to lowing quotation from Mr Nicholson † concerning final Nat. Phil. causes, which sums up all that can be faid with propriety Vol. 1. 163. infavour of the doctrine in question .- " The purposes or motives (fays he) which determine the actions of intelligent brings, and produce their effects in a manner fimilar to the operation of the laws of nature, or the properties of matter in cales where thought is not supposed to be concerned, are called final causes. In the works of nature we behold enough of exquisite contrivance, and can fee far enough into many final causes, to convince us that the arrangement of the univerle has been made, and probably still is occasionally adjusted, by a Being whose intelligence and power are immensely beyoud what we possels. To judge properly of his intentions, or, in other words, to be equal to the talk of exploring final causes, requires no less than a perfect knowledge and recollection of every purpose to which the objects around us may be applied, together with a clear conception of the ideas of fitness and order that form the prototypes in the mind of that Great Being who directs their motions. These considerations show the absurdity of attempting to explain the final causes of every event we see; but they by no means require that we should neglect them in cases where we have reason to believe that we understand the phenomena, and have sufficient experience to be affured that we differn the principal, or at least one of the principal, purposes to which things may have been destined. Thus it is scarcely to be imagined that we can err in concluding, that the eyes, ears, legs, wings, and other parts of animals, were made for the purpoles of feeing, hearing, walking, flying, and so forth. Neither can we avoid inferring, that the Power who confiruded living creatures with mouths, teeth, and organs to digest and assimilate food for their nutriment, did likewise form other organized bodies, which we call vegetables, for the express purpose of affording that food. It is needless to multiply instances. We cannot avoid see- Conclusions ing them every moment; and their effect is so striking, from the that we are infenfibly forced from analogy to allow the existence of a final cause in all cases, whether we are

able to discover it or not.

" On this ground, an inquiry into the final causes of the planetary bodies offers itself to our confidera. Of the vation. The earth is shown to be a planet in circum-rious chflances very fimilar to the other five; we know its mates of final cause to furner a number of inhabitance. And the planets. final cause—to support a number of inhabitants: And by analogy we may conclude, that the others are also habitable worlds; though, from their different proportions of heat, it is credible that beings of our make and temperature could not live upon them. However, even that can fearcely be affirmed of all the planets; for the warmest climate on the planet Mars is not colder than many parts of Norway or Lapland are in the spring or autumn. Jupiter, Saturn, and the Georgium Sidus, it must be granted, are colder than any of the inhabited parts of our globe. The greatest heat on the planet Venus exceeds the heat on the islandof St Thomas on the coast of Guinea, or Sumatra in the East Indies, about as much as the heat in those places exceeds that of the Orkney islands, or the city of Stockholm in Sweden: therefore, at 60° north latitude on that planet, if its axis were perpendicular to the plane of its orbit, the heat would not exceed the greatest heat on the earth; and of course vegetation like ours might be there carried on, and animals of the species on earth might sublist. If Mercury's axis be supposed to have a like position, a circle of about 20° diameter round each pole would enjoy the fame temperature as the warmer regions of the earth, though in its hottest climate water would continually boil, and most inflammable substances would be parched up, destroyed, or converted into vapour. But it is not at all necessary that the planet should be peopled with animals like those on the earth; the Creator has doubtless adapted the inhabitants of each to their fituation.

" From the observations that have been just made, Comparia better idea may be formed of the proportions of heat ion of the on the planets than can be conveyed by numbers. It light of the will not, however, be remote from our purpose to superior compare the light of the superior planets with that of planets our day; from whence it will appear, that they are day, by no means in a flate of darkness, notwithstanding their great distance from the sun. This might be instanced by several different methods; as by the fun's light admitted into a dark chamber, and received on paper with different degrees of obliquity; by a greater or less number of candles brought into a room for the purpose of illuminating it with various degrees of light; or by various optical methods that need not here be described. It will be sufficient for the illustration of the subject, to compare their different proportions of light with that of a moonthine night at the time of full.

"When the moon is visible in the day-time, its light is fo nearly equal to that of the lighter thin clouds, that it is with difficulty diffinguished among them. Its light continues the fame during the night; but the absence of the sun suffering the pupil of the eye to dilate itself, it becomes more conspicuous. It therefore follows, that if every part of the sky were equally

Appearan-

Conclusions equally luminous with the moon's disk, the light would from the be the fame as if in the day-time it were covered with Appearant the thin clouds above mentioned. This day light is consequently in proportion to that of the moon as the whole furface of the sky or visible hemisphere is to the furface of the moon; that is to fav, nearly as 90,000 to 1. The light of the Georgium Sidus being to that of the earth as 0.276 to 100, will be equal to the effect of 248 full moons. Jupiter's day will equal the light of 3,330 moons; and that of Mars will require 38,700, a number fo great that they would almost touch one another. It is even probable, that the comets in the most distant parts of their orbits enjoy a degree of light much exceeding moonfline."

Of all the celestial bodies, comets have given rife to the greatest number of speculations and conjectures. Their strange appearance has in all ages been a matter of terror to the vulgar, who uniformly have looked upon them to be evil omens and forerunners of war, pestilence. &c, Others, less superstitious, supposed them to be meteors raifed in the higher regions of the air. But we find that some part of the modern doctrine concerning them had been received into the ancient Italic and Pythagorean schools: for they held them to by the an- be fo far of the nature of planets, that they had their cients to be periodical times of appearing; that they were out of fight for a long time, while they were carried aloft at an immense distance from the earth, but became visible when they descended into the lower regions of the air,

when they were nearer to us.

opimon them.

planets.

These opinions were probably brought from Egypt, from whence the Greeks borrowed great part of their learning. However, it feems not to have been gene-Aristotle's rally received: for Aristotle, who mentions it, afferted that the heavens were unchangeable, and not liable to concerning generation or corruption. Comets, therefore, which he believed to be generated when they first made their appearance, and destroyed when they vanished from our fight, he maintained could not be heavenly bodies, but rather meteors or exhalations raised into the upper regions of the atmosphere, where they blazed out for a while, and disappeared when the matter of which they were formed was confumed. Seneca, who lived in the first century, mentions Apollonius of Myndus, a very careful observer of natural causes, to have been of the fame fentiments with the most ancient Greek philosophers with regard to comets. He himself had feen two ; one in the reign of Claudius, the other in that of Mero; besides another which he saw while a boy, before the death of Augustus. He plainly intimates, that he thought them above the moon; and argues strongly against those who supposed them to be meteors, or held other abfurd opinions concerning them; declaring his belief that they were not fires fuddenly kindled, but the eternal productions of nature. He points out also the only way to come at a certainty on this subject, viz. by collecting a number of observations concerning their appearance, in order to discover whether they return periodically or not. " For this purpose (says he) one age is not sufficient; but the time will come when the nature of comets and their magnitudes will be demonstrated, and the routes they take, so different from the planets, explained. Polerity will then wonder that the preceding ages

should be ignorant of maters so plain and easy to be Conclusions known."

For a long time this prediction of Seneca feemed foregoing very unlikely to be fulfilled. The great authority which Aristotle maintained for many ages, determined them to be nothing but meteors casually lighted up in the air; though they were manifestly at a great height, not only above the clouds, but subject to the diurnal revolution of the earth. In the dark and fuperstitious ages, they were held to be the forerunners of every kind of calamity, and were supposed to have different degrees of malignity according to the shape they assumed; from whence also they were differently denominated. Thus, some were said to be bearded, some hairy; fome to represent a beam, sword, or spear; others a target, &c.; whereas modern altronomers ac-Only one knowledge only one species of comets, and account for species of their different appearances from their different situa-them existe.

tions from the fun and earth.

It was not till some time after people began to Kepler and throw off the fetters of superstition and ignorance Bodin's owhich had so long held them, that any rational hypo-pinion of thefis was formed concerning comets. Kepler, in them. other respects a very great genius, indulged the most extravagant conjectures, not only concerning comets, but the whole fystem of nature in general. The planets he imagined to be huge animals who fwam round the fun by means of certain fins acting upon the ethereal fluid, as those of sines do on the waters and agreeable to this notion, he imagined the comets to be monitrous and uncommon animals generated in the celetial fpaces; and he explained how the air engendered them by an animal faculty. A yet more ridiculous applicant if possible, was that of John Bodin, a learned man of France in the 16th century. He maintained that comets " are spirits, which have lived on the earth innumerable ages, and being at last arrived on the confines of death, celebrate their last triumph, or are recalled to the firmament like shining stars! This is followed by famine, plague, &c. because the cities and people destroy the governors and chiefs who appeale the wrath of God." This opinion (he fays) he borrowed from the philosopher Democritus, who imagined them to be the fouls of famous heroes: but that being irreconcilable with Bodin's Christian sentiments, he was obliged to suppose them to be a kind of genii, or spirits subject to death, like those so much mentioned in the Mahometan fables. Others, again, have denied even the existence of comets, and maintained that they were only falle appearances occasioned by the refraction or reflection of the light.

The first rational conjecture we meet with is that of Bernouilli's James Bernouilli, an Italian astronomer, who imagined opinion. them to be the fatellites of some very distant planet. which was invisible to us on account of its distance, as were also the satellites, unless when in a certain part of their course.

Tycho Brahe was the first who restored the co-True docmets to their true rank in the creation. Before his trine contime, feveral comets had been observed with tolerable cerning them reviexactness by Regiomontanus, Appian, Fabricius, and ved by Tye others; yet they all thought them below the moon cho Brahe. But Tycho, being provided with much better inftruments, fet himfelf with great diligence to observe the

famous

Conclusions famous comet of 1577; and from many careful obserfrom the vations, deduced that it had no fensible diurnal paralforegoing lax; and therefore was not only far above the regions of our atmosphere, but much higher than the moon. But though few have come to near the earth as to have any diurnal parallax, all of them have what may be called an annual parallax; that is, the revolution of the earth in her orbit causes their apparent motion to be very different from what it would be if viewed from the fun; and this shows them to be much nearer than the fixed flars, which have no fuch parallax. Kepler, the disciple of Tycho, notwithstanding his ridiculous conjecture already mentioned, was very attentive to the motions of the comets, and found that they did not move in straight lines, as had been supposed. He showed that their paths were concave towards the fun, and supposed them to move in parabolic trajectories.

Their true motion, however, was only discovered

Their mo-

tion exactly from the observations made by Sir Isaac Newton on determined the great comet of 1680. This descended almost perby Sir Isaac pendicularly towards the sun with a prodigious velocity; ascending again with the same velocity retarded, as it had been before accelerated. It was feen in the morning by a great number of astronomers in different parts of Europe, from the 4th to the 25th of November, in its way towards the fun; and in the evening from the 12th of December to the 9th of March following. The many exact observations made on this comet enabled Sir Isaac Newton to determine that they are a kind of planets which move in very eccentric ellipses: and this opinion is now looked upon to be certainly established. It was opposed, however, by M. de la Hire, and some other French philosophers; and it is evident that the whole dispute now turned on mere practical observation. If the return of any comet could be predicted, and its periodical time calculated like that of a planet, then the doctrine might be concluded Dr Halley certainly true, but not otherwise. Dr Halley therefore predicts a fet himself to collect all the observations he could on comets; and afterwards calculated the periodical times of 24 of them, on a supposition of their being paraboles: but afterwards found that they agreed better with the supposition of their motion being performed in very eccentric elliptical orbits. On this he calculated a table of their elements; from which it was manifest that they were not comprehended in the zodiac, fome of them making an angle of upwards of 80° with the ecliptic.

171 Periodical times of consets determined.

turn.

By computations founded on these elements, the Doctor concluded that the comet of 1682 was the fame which had appeared in 1607 and 1531; that it had a period of 75 or 76 years; and he ventured to foretel that it would return about the year 1758. The comet which appeared in 1661 was supposed to be the fame with that of 1532, and to have a period of 120 years; and from the equality of periods, and fimilitude of appearances, it was concluded, that the great comet of 1680 was the same which had appeared in 1106 in the time of Henry I. and the confulare of Lampadius and Orestes about the year 531, and in the year 44 B. C. before Julius Cæsar was murdered; and thence concluded that its period was 575 years. Mr Dunthorne, however, has endeavoured to show from a MS. in Pembroke hall library, that the comet of 1106 could not be the same with that of 1680: but M. de la Lande thinks the four appearer restricted by Conclusions Dr Halley stronger proofs than a single observation, from the which might be very faulty.

for going

Since the time of Dr Halley, other astronomers have Appearancalculated the elements of 25 other comets; all of which, excepting one of three which appeared in 1759, and which differs but little from that of 1531, 1607, and 1682, and is therefore accounted the same, differ very much from each other; fo that we cannot help concluding them all to be different, and that the number of these bodies is very great. "It is not, how-Why coever, unlikely (fays Dr Long), from the immense inter-mets may val between the orbit of Saturn and the nearest fixed foretimes stars, that many of them have not descended into the even in planetary regions fince they have been looked upon as their period celestial bodies, and observed accordingly: besides, it helion. may often happen, that a body may finish its whole period without being observed by us, on account of the unfavourable fituation of the earth in her orbit when the comet is in its perihelion. Thus, if the comet be either behind or before the fun, or nearly fo, it must be above our horizon in the day time, and confequently invifible, except the fun should at that time be in a total eclipse; for then the comet might be seen near the fun, as well as the stars and planets are: and this case is said to have happened; for Seneca relates from Poslidonius, that a comet was feen when the fun was eclipfed, which had before been invisible by being near

that luminary." A greater number of comets are feen in the hemi. Why more fphere towards the fun than in the opposite; the reason are seen in of which will easily appear from fig. 97. wherein S the hemi-represents the sun, E the earth, ABCD the sphere of wards the the fixed stars: and because comets either do not re-fun than in flect light enough to be visible, or emit tails conspi-the oppocuous enough to attract our notice, till they come with-fite. in the planetary regions, commonly a good way within the sphere of Jupiter, let KLMN be a sphere concentric to the fun, at fuch a diffance from him, that no comet can be feen by us till it come within that diflance; through E draw the plane BD perpendicular to SE, which will divide the sphere KLMN into two hemispheres, one of which, BCD, is toward the sun. the other, DAB, opposite. Now it is manifest, that the spherical portion LMN, which is in the hemifphere BCD towards the fun, is larger than the portion NKL in the hemisphere opposite to him; and confequently a greater number of comets will appear in the

hemisphere BCD than in that marked DAB. Though the orbits of all comets are very eccentric Great difellipses, there are vast differences among them except ferences in ing Mercury, there are no great differences among the the excenplanets either as to the eccentricity of their orbits, or the orbits the inclination of their planes; but the planes of fome of comets. comets are almost perpendicular to others, and some of their ellipses are much wider than others. The narrowest ellipses of any comet hitherto observed was that of 1680. There is also a much greater inequality in the motion of the comets than of the planets; the velocity of the former being incomparably greater in their perihelion than in their aphelion; but the planets are but very little accelerated.

Astronomers are now generally agreed, that comets Opiniors are opaque bodics, enlightened by the fus Hevelius, concerning in a large work, wherein he gives the opinion of vari-their fulous ftance.

a curve.

ces.

Conclusions others in their neighbourhood. Since therefore this from the fact is supported by observations, what can be a plainer Appearan proof that the matter of a comet's tail has no power of reflecting the rays of light, and consequently that it must be a self-shining substance? But the same thing will further appear, from confidering that bodies reflect and refract light by one and the same power; and therefore if comets tails want the power of refracting the rays of light, they must also want the power of reflecting them. Now, that they want this refracting power appears from hence: If that great column of transparent matter which forms a comet's tail, and moves either in a vacuum or in some medium of a different density from its own, had any power of refracting a ray of light coming through it from a star to us, that ray must be turned far out of its way in pasfing over the great distance between the comet and the carth; and therefore we should very fensibly perceive the smallest refraction that the light of the stars might fuffer in passing though a comet's tail. fequence of fuch a refraction must be very remarkable: the flars that lie near the tail would, in some cases, appear double; for they would appear in their proper places by their direct rays, and we should see their images behind the tail, by means of their rays which it might refract to our eyes; and those stars that were really behind the tail would disappear in some fituations, their rays being turned afide from us by refraction. fhort, it is easy to imagine what strange alterations would be made in the apparent places of the fixed flars by the tails of comets, if they had a power of refracting their light, which could not fail to be taken notice of if any fuch ever happened. But fince aftronomers have not mentioned any fuch apparent changes of place among the flars, I take it for granted that the stars seen through all parts of a comet's tail appear in their proper places, and with their usual colours; and confequently I infer, than the rays of light fuffer no refraction in paffing through a comet's tail. And thence I conclude (as before), that the matter of a comet's tail has the power of refracting or reflecting the rays of light, and must therefore be a lucid or self-shining substance.

121 Sir Mane's fended.

But whatever probability the Doctor's conjecture acrount de-concerning the materials whereof the tails are formed may have in it, his criticism on Sir Isaac Newton's account of them feems not to be just: for that great philosopher supposes the comets to have an atmosphere peculiar to themselves; and consequently, in their nearest approaches to the fun, both comet and atmosphere are immerica in the atmosphere of that luminary. In this case, the atmosphere of the comet being prodigiously heated on the fide next to the fun, and confequently the equilibrium in it better, the denfer parts will continually pour in from the regions farthest from the fun; for the same reason, the more rarefied part which is before will continually fly off opposite to the sun, being displaced by that which comes from behind; for though we must suppose the comet and its atmosphere to be heated on all fides to an extreme degree, yet still that part which is farthest from the sun will be less hot, and confequently more denfe, than what is nearest to his body. The confequence of this is, that there must be a conflict stream of dense atmosphere descending towards the fun, and anothe ritream of rarefied vapours

. .

and atmosphere ascending on the contrary fide; just as, Conclusions in a common fire, there is a constant stream of dense from the air descending, which pushes up another of raresed air, same, and smoke. The resistance of the solar cea. atmosphere may indeed be very well supposed to occafion the curvature observable in the tails of comets, and their being better defined in the fore part than behind; and this appearance we think Dr Hamilton's Dr Hamilhypothesis is incapable of solving. We grant, that ton's hypothere is the utmost probability that the tails of comets the sinfufare streams of electric matter; but they who advance ficient. a theory of any kind ought to folve every phenomenon, otherwise their theory is insufficient. It was incumbent on Dr Hamilton, therefore, to have explained how this stream of electric matter comes to be bent into a curve; and also why it is better defined and brighter on the outer fide of the arch than on the inner. This, indeed, he attempts in the following manner: " But that this curvature was not owing to any refisting matter appears from hence, that the tail must be bent into a curve though it met with no refishance : for it could not be a right line unless all its particles were projected in parallel directions, and with the fame velocity, and unless the comet moved uniformly in a right line. But the comet moves in a curve, and each part of the tail is projected in a direction opposite to the fun, and at the same time partakes of the motion of the comet; so that the different parts of the tail must move on in lines which diverge from each other; and a line drawn from the head of a comet to the extremity of the tail, will be parallel to a line drawn from the fun to the place where the comet was when that part of the tail began to ascend, as Sir Hand observes; and fo all the chords or lines drawn from the head of the comet to the intermediate parts of the tail, will be respectively parallel to lines drawn from the fun to the places where the comet was when thele parts of the tail began to ascend. And therefore, fince these chords of the tail will be of different lengths, and parallel to diffent lines, they mult make different angles with a great circle passing through the fun and comet, and confequently a line passing through their extremities will be

" It is observed, that the convex side of the tail which is turned from the fun is better defined, and shines a little brighter, than the concave fide. Sir Isaac accounts for this, by faying, that the vapour on the convex fide is frether (that is, has afcended later) than that on the concave fide; and yet I cannot fee how the particles on the convex fide can be thought to have afcended later than those on the concave side which may be nearer to the head of the comet. I think it rather looks as if the tail, in its rapid motion, met with some flight refistance just sufficient to cause a small condensation in that fide of it which moves foremost, and which would occasion it to appear a little brighter and better defined than the other fide; which flight refiftance may arise from that subtile, ether which is supposed to be dispersed through the celeftial regions, or from this very electric matter dispersed in the same manner, if it be different from the ether."

On the kill part of this observation we must remark, that though a flight reliftance in the othereal medium would have ferved Sir Isaac Newton's turn, it will by no means ferve Dr Hamilton's; for though a stream of

Conclusions water or air may be easily destroyed or broken by refrom the sistance, yet a stream of electric matter seems to set foregoing every obstacle at defiance. If a sharp needle is placed on Appearanthe conductor of an electric machine, and the machine fet in motion, we will perceive a small stream of electric matter iffung from the point; but though we blow against this stream of fire with the utmost violence, it is impossible either to move it, or to brighten it on the fide against which we blow. If the celestial spaces then are full of a fubtile other capable of thus affecting a stream of electric matter, we may be sure that it alto will refift very violently; and we are then as much difficulted to account for the projectile motion continuing amidft fuch violent reliffance; for if the ether refifts the tail of the comet, it is impossible to prove that it doth not refift the head also.

183 Ek chric

This objection may appear to some to be but weakmatter not ly founded, as we perceive the electric fluid to be enalways paf-dowed with fuch extreme fubtility, and to yield to the impression of folid bodies with such facility, that we eafily imagine it to be of a very passive nature in all cases. But it is certain, that this fluid only shows itfelf passive where it passes from one body into another, which it feems very much inclined to do of itself. It will also be found, on proper examination of all the phenomena, that the only way we can manage the electric fluid at all is by allowing it todirect its own motions. In all cases where we ourfelves attempt to assume the government of it, it shows it felf the most untractable and hubborn being in nature. But these things come more properly under the article Electricity, where they are fully confidenced. Here it is sufficient to observe, that is sufficient to observe, that is sufficient to observe, the sufficient of electric matter resists air, and from the precioned of electric repullion we are fure that one fireast of clectric matter relifts another; from which we may be also certain, that if a stream of electric shatter moves in an aerial fluid, such fluid will refist it; and we can only judge of the degree of relitance it meets with in the heavens from what we observe on earth. Here we see the most violent blast of air has no effect upon a fiream of electric fluid; in the celefial regions, either air or some other fluid has an effect upon it according to Dr Hamilton. The refiltance of that fluid, therefore, must be greater than that of the most violent blast of air we can imagine.

As to the Doctor's method of accounting for the curvature of the comet's tail, it might do very well on Sir Isaac Newton's principles, but cannot do so on his. There is no comparison between the celerity with which rarefied vapour afcends in our atmosphere, and that whereby the electric fluid is discharged. The velocity of the latter feems to equal that of light; of confequence, supposing the velocity of the comet to be equal to that of the earth in its annual course, and its tail equal in length to the distance of the fun from the earth, the curvature of the tail could only be to a straight line as the velocity of the comet in its orbit is to the velocity of light, which, according to the calculations of Dr Bradley, is as 10,201 to 1. The apparent curvature of fuch a comet's tail, therefore, would at this rate only be To for part of its visible length, and thus Prodigious would always be impurceptible to us. The velocity of velocity of comets is indeed fometimes inconceivably great. Mr a comet ob- Brydone observed one at Palermo, in July 1770, which ferved by Mr Bry- in 24 hours described an arch in the heavens upwards

of 50 degrees in length; according to which he fup-Conclusions pofes, that if it was as far diffant as the fun, it mult from the have moved at the rate of upwards of 60 millions of Appearanmiles in a day. But this comet was attended with no

ces. tail, fo that we cannot be certain whether the curvature of the tails of these bodies corresponds with their velocity or not.

The near approach of fome comets to the fun fubjects them to intense and inconceivable degrees of heat. Newton calculated that the heat of the comet of 1680 Vehement must have been near 2000 times as great as that of red hear of the hot iron. The calculation is founded upon this prin-comet of

ciple, that the heat of the fun falling upon any body 1680. at different distances is reciprocally as the squares of those distances; but it may be observed, that the cffect of the heat of the fun upon all bodies near our earth depends very much on the constitution of those bodies, and of the air that furrounds them. "The comet in question (fays Dr Long) certainly acquired a prodigious heat; but I cannot think it came up to what the calculation makes it: the effect of the strongeft burning-glass that has ever been made use of was the vitrification of most bodies placed in its focus. What would be the effect of a full greater heat we can only conjecture; it would perhaps fo difunite the parts as to make them fly off every way in atoms. This comet, according to Halley, in passing thro' its southern node, came within the length of the fun's femidiameter of the orbit of the earth. Had the earth then been in the part of her orbit nearest to that node, their mutual gravitation must have caused a change in the plane of the orbit of the earth, and in the length of our year: he adds, that if so large a body with so rapid a motion as that of this comet were to firske against the earth, a thing by no means impossible, the shock might reduce this beautiful frame to its original chaos."

We must not conclude this account without observing, that Whiston, who, from Flamstead's measure of its apparent diameter, concluded the nucleus of the comet to be about ten times as big as the moon, or equal to a fourth part of the earth, attributes the universal deluge in the time of Noah to the near approach thereof. His opinion was, that the earth passing thro' the atmofphere of the comet, attracted therefrom great part of the water of the flood; that the nearness of the comet raifed a great tide in the fubterraneous waters, fo that the outer crust of the earth was changed from a spherical to an oval figure; that this could not be done without making fiffures and cracks in it, through which the waters forced themselves by the hollow of the earth being changed into a lefs capacious form; that along with the water thus foucezed up on the furface of the earth, much flime or mud would rife; which, together with the groffer part of the comet's atmosphere, would, after the subfiding of the water, partly into the fiffures and partly into the lower parts of the earth to form the fea, cover all over, to a confiderable depth, the antediluvian earth. Thus he accounts for trees and bones of animals being found at very great depths in the earth. He also held that, before the fall, the earth revolved round the fun in the plane of the ecliptic, keeping always the same points of its surface towards the same fixed stars. By this means, as every meridian would come to the fun but once in every revolution, a day and a year were then the fame: but

done.

3 N 2

Appearen-

Conclusions that a comet striking obliquely upon some part of the from the earth gave it the diurnal rotation; that the antediluvian year confifted of 360 days; but that the additional matter deposited upon the earth from the atmo-Sphere of the comet at the flood so retarded the revolution thereof round the fun, that it is not now performed in less than 365 days and about a quarter. The fame comet he thought would probably, coming near the earth when heated in an immense degree in its peribelion, be the instrumental cause of that great cata-Arophe, the general conflagration, foretold in the fa-

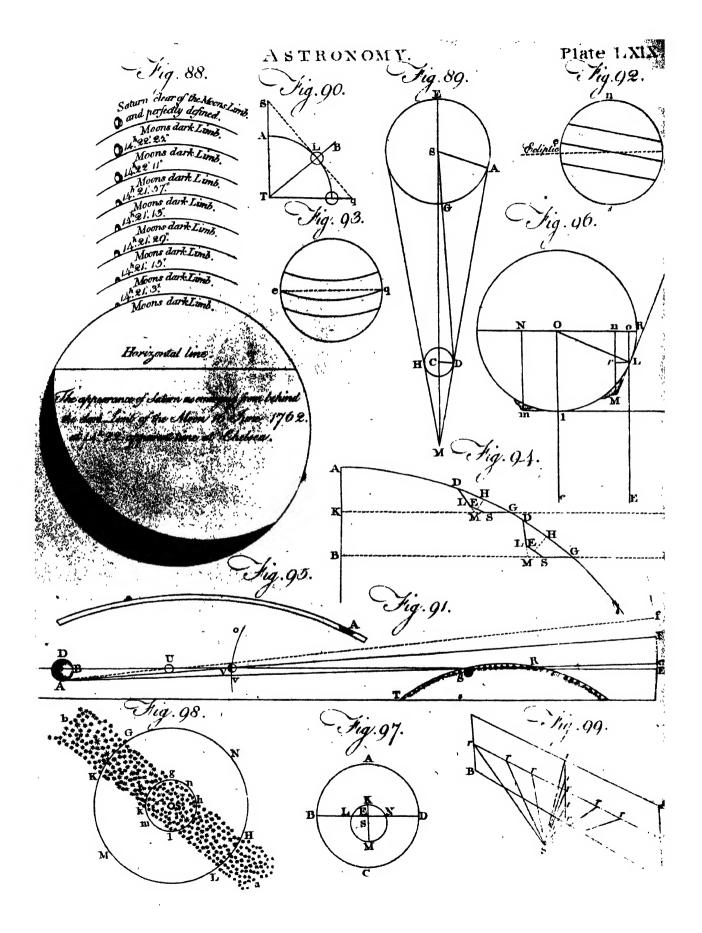

186 Conjectures mature of ometr.

cred writings and from ancient tradition. These conjectures lead us to speak somewhat more of Hevelius particularly concerning the nature of the comets, and the purpoles they may possibly answer in the creation. cerning the Hevelius, in order to account for the various appearances of the nucleus already related, supposed that they were composed of several masses compacted together with a transparent fluid interspersed, but the apparent changes in the nucleus may be only on the furface: comets may be subject to spots as the planets are; and the valtly different degrees of heat they go through may occasion great and fudden changes, not only in their furfaces, but even in their internal frame and texture. Newton places all these apparent changes to the atmosphere that environs them; which must be very denfe near the furface, and have clouds floating therein. It was his opinion, that the changes mentioned may all be in the clouds, not in the nucleus. This laft indeed he looked upon to be a body of extreme fohdity, in order to fullain such an intense heat as the comets are forectimes deflined to undergo; and that, not athilanding their running out into the immense regions of space, where they were exposed to the most intense degrees of cold, they would hardly be cooled again on their return to the fun. Indeed, according to his calculation, the comet of 1680 must be for ever in a flate of violent ignition. He hath computed that a globe of red-hot iron of the fame dimentions with the earth, would fearce be cool in 50,000 years. If then the comet be supposed to cool 100 times faster than red-hot iron, as its heat was 2000 times greater, it must require upwards of a million of years to cool it. In the short period of 575 years, therefore, its heat will be in a manner fearce diminithed; and, of confequence, in its next and every fucceeding revolution, it must acquire an increase of heat: fo that, fince the creation, having received a proportional addition in every fucceeding revolution, it must now be in a flate of ignition very little inferior to that of the fun stielf. Sir Isaac Newton hath farther concluded, that this comet must be considerably retarded in every succeeding revolution by the atmofphere of the fun within which it enters; and thus must continually come nearer and nearer his body, till at last at fulls into it. This, he thinks, may be one use of the comets, to furnish fuel for the fun, which otherwise would be in danger of wasting from the continual emiffion of its light.

He adds, that for the confervation of the water and moisture of the planets, comets seem absolutely requifite; from whose condensed vapours and exhalation all the moisture which is spent in vegetation and putrefuttion, and turned into dry earth, &c. may be resupplied and recruited; for all vegetables grow and Conclusions increase wholly from fluids; and again, as to their from the prested part, turn by nutrefaction into earth, an earth, greatest part, turn by putrefaction into earth; an earthy Appearan-flime being perpetually precipitated to the bottom of ces. putrefying liquors. Hence the quantity of dry earth mult continually increase, and the moilture of the globe decrease, and be quite evaporated, if it have not a continual supply from some part or other of the universe. " And I suspect (adds our great author), that the spirit, which makes the finest, subtilest, and best part of our air, and which is absolutely requisite for the life and being of all things, comes principally from the comets."

Mr Brydone observes, that the comets without tails feem to be of a very different species from thole which have tails: To the latter, he fays, they appear to bear a much less resemblance than they do even to planets. He tells us, that comets with tails have fel-Mr Brydom been visible but on their recess from the fun : that done's conthey are kindled up, and receive their alaiming appear concerning ance, in their near approach to this glorious luminary; comets but that those without tails are seldom or never seen without but on their way to the fun; and he does not recollect tails. any whose return has been tolerably well ascertained. " I remember indeed (fays he), a few years ago, a fmall one, that was faid to have been discovered by a telescope after it had passed the fun, but never more became visible to the naked eye. This affertion is easily made, and nobody can contradict it; but it does not at all appear probable that it should have been so much lefs lummous after it had passed the fun than before it. approached him: and I will own to you, when I have heard that the return of these comets had escaped eyes of the most acute astronomers. I have been total ed to think that they did not return at all, but we absorbed in the body of the sun, which their violent motion towards him seemed to indicate." He then attempts to account for the continual emission of the fun's light without wafte, by supposing that there are numberless bodies throughout the universe that are attracted into the body of the fun, which ferve to supply the waste of light, and which for some time remain obscure and occasion spots on his surface, till at last they are perfectly dissolved and become bright like the rest. This hypothesis may account for the dark spots becoming as bright, or even brighter, than the rest of the disk, but will by no means account for the brighter fpots becoming dark. Of this comet too, Mr Brydone remarks, that it was evidently furrounded by an atmosphere which refracted the light of the fixed stars, and seemed to cause them change their places as the comet came near them.

A very strange opinion we find fet forth in a book Mr Cole's entitled " Observations and Conjectures on the Nature hypothesis. and Properties of Light, and on the Theory of Comets, by William Cole." This gentleman supposes that the comets belong to no particular system; but were originally projected in fuch directions as would successively expose them to the attraction of different centres, and thus they would describe various curves of the parabolic and the hyperbolic kind. This treatife is written in answer to some objections thrown out in Mr Brydone's Tour, against the motions of the comets by means of the two forces of gravitation and projection,

Conclusions which were thought sufficient for that purpose by Sir from the Isaac Newton; of which we shall treat as fully as our foregoing limits will allow in the next fection.

189 Of the periodic il tii 168, &C. of the CUMILLE.

The analogy between the periodical times of the planets and their diffances from the fun, discovered by Kepler, takes place also in the comets. In confequence of this, the mean distance of a comet from the fun may be found by comparing its period with the time of the earth's revolution round the fun. Thus the period of the comet that appeared in 1531, 1607, 1662, and 1759, being about 76 years, its mean diflance from the fun may be found by this proportion: As 1, the fquare of one year, the earth's periodical time, is to 5776 the square of 76, the comet's periodical time; fo is 1,000,000, the cube of 100 the earth's mean distance from the fun, to 5,776,000,000, the cube of the comet's mean distance. The cube root of this last number is 1794, the mean distance itself in such parts as the mean diffance of the earth from the fun contains 100. If the perihelion distance of this comet, 58, be taken from 3588 double the mean distance, we shall have the aphelion distance, 3530, of such parts as the distance of the earth contains 100; which is a little more than 35 times the distance of the earth from the fun. By a like method, the aphelion distance of the comet of 1680 comes out 138 times the mean distance of the earth from the fun, supposing its period to be 575 years; so that this comet, in its aphelion, goes more than sa'times the distance from the sun that Saturn does. Euler computes the orbit of this comet from three of Finantisad's observations taken near together, compared with a fourth taken at some di-than from the other three; and from thence concludes the period to be a little more than 170 years. "It form the little in the little more than 170 years. "It form the little busy surprising, (says Dr Long), that, on and Helley, he should bring out a period so very different from what those great men have determined: but it is the less to be wondered at, if we consider how fmall a portion of the comet's orbit lay between the most distant places used in this computation, or indeed that could be had for that purpose; so small, that the form of the ellipsis cannot be found with precision by this method, except the comet's places were more exactly serified than is possible to be done: and that he does not pretend to confirm his determination of the period, by pointing out and comparing together any former appearances of this comet; a method which Newton recommended as the only one whereby the periodical times and transverse diameters of the orbits of the comets can be determined with accuracy."

The period of the comet in 1744 is much longer than even that of 1680. Mr Betts, in attempting to compute the transverse axis of its orbit, found it come out so near infinite, that, though the orbit showed itself in this manner to be a very long one, he found it imposfible to calculate it without fome observations made after its perihelion. Halley, after he had finished his table of comets, found fuch a similitude in the elements the return of those of 1531, 1607, and 1682, that he was induof comets, ced to believe them to be returns of the same comet in an elliptic orbit : but as there was fuch a difference in their periodical times and inclinations of their orbits as seemed to make against this opinion; and as the observations of the first of them in 1531 by Apian,

and the second in 1607 by Kepler, were not exact e- Conclusion nough to determine so nice a point when he mit pub- from the lished his synopsis in 1705; he only mentioned this as Appearan-a thing probable, and recommended it to posterity to ces. watch for an appearance of the same in 1758. Afterwards, looking over the catalogue of ancient comets, and finding three others at equal intervals with those now mentioned, he grew more positive in his opinion; and knowing a method of calculating with eafe a motion in an elliptic orbit, how eccentric foever it might be, inflead of the parabolic orbit which he had given for the comet of 1652, he fet about adapting the plan of that orbit to an ellipsis of a given frace and magnitude, having the fun in one of its foci, fo as to tally with the observations of that comet made by Flamflead with great accuracy, by the help of a very large fextant. He likewise corrected the places of the comet of 1531 from Apian, and those of the comet 1607 from Kepler and Longomontanus, by rectifying the places of the flurs they had made use of, and found those places agree as well with the motion in such an ellipsis as could be expected from the manner of obferving of these altronomers and the imperfections of their instruments. The greatest objection to this theory was some difference in the inclination of the orbits, and that there was above a year's difference between the two periods. The comet of 1531 was in Why the

its perihelion August 24.; that of 1607, October 16.; periodical and that of 1682, September 4.: so that the first of return of these periods was more than 76, the latter not quite comets may 75 years. To obviate this, he reminds his readers of unequal an observation made by him of the periodical revolu-intervalation of Saturn having at one time been about 13 days longer than at another time; occasioned, as he supposed, by the near approach of Saturn and Jupiter, and the mutual attraction and gravitation of the two planets: and observes, that in the summer of the year 1681, the comet in its delcent was for some time fo near Jupiter, that its gravitation towards the planet was one fiftieth part of its gravitation towards the fan. Th., he concluded, would cause a change in the inclination of its orbit, and also in the velocity of its motion: for by continuing longer near the planet Jupiter on the fide most remote from the fun, its velocity would be more increased by the joint forces of both those bodies, than it would be diminished by them acting contrariwife, when on the fide next the fun where its motion was fwiftelt. The projectile motion being thus increafed, its orbit would be enlarged, and its period lengthened; fo that he thought it probable it would not return till after a longer period than 76 years, about the end of the year 1758 or beginning of

As Halley expressed his opinion modestly, though clearly enough, that this comet would appear again about the end of 1758, or the beginning of the following year, M. de la Lande prettods he must have been at a loss to know whether the period he foretold would have been of 75 or of 76 years; that he did not give a decilive prediction, as if it had been the refult of calculation; and that, by confidering the affair in fo loofe a manner as Halley did, there was a good deal of room for objecting to his reasoning. After these reflections, he is very large in his commendation of the performance of Mr Clairault; who, he fays, not

Dr Halley

fonelulions only calculated firicity the effect of the attraction of from the Jupiter in 1681 and 1683, when the comet was again foregoing Jupiter in 1081 and 1083, when the comet was again sprearan near Jupiter, but did not neglect the attraction of that planet when the comet was most distant; that he confidered the uninterrupted attractions of Jupiter and Saturn upon the fun and upon the comet, but chiefly the attraction of Jupiter upon the fun, whereby that luminary was a little displaced, and gave different elements to the orbit of the comet. By this method he found the comet would be in its perihelion about the aniddle of April: but that, on account of some small quantities necessarily neglected in the method of approximation made use of by him, Mr Clairault defired to be indulged one month; and that the comet came just 30 days before the time he had fixed for its appearance.

That comets may have their motion disturbed by the planets, especially by the two largest, Jupiter and Saturn appears by an inftance just now mentioned. They may also affect one another by their mutual gravitation when out of the planetary regions; but of this we can take no account, nor can we estimate the resist. ance of the ether through which they pass; and yet both these causes may have some influence on the inclination of their orbits and the length of their periods.

ixed flars

Thus much concerning the bodies of which our foapposed to lar fystem is composed. But the conjectures of astronomers have reached even beyond its boundaries: they have supposed every one of the innumerable multitude of fixed stars to be a fun attended by planets and comets, each of which is a habitable world like our own; fo that the universe may in some measure be represented by fig. 161. where several adjacent systems are marked. The strongest argument for this hypothefis is, that they cannot be magnified by a telescope on account of their extreme diffance; whence we must conclude that they shine by their own light, and are therefore as many funs: each of which we may suppose to be equal if not superior, in lustre and magnitude to our own. They are not supposed to be at equal diflances from us, but to be more remote in proportion to their apparent smallness. This supposition is necessary to prevent any interference of their planets; and thus there may be as great a distance between a flar of the first magnitude and one of the second apparently close to it, as between the earth and the fixed stars first mentioned.

101 ppofed, om the triable iture of e stars.

Those who take the contrary side of the question affirm, that the disappearance of some of the fixed stars is a demonstration that they cannot be funs, as it would be to the highest degree absurd to think that God would create a fun which might disappear of a sudden, 194 and leave its planets and their inhabitants in endless ncerning night. Yet this opinion we find adopted by Dr Keill, who tells us, "It is nowife improbable that thefe stars lost their brightness by a prodigious number of spots which entirely covered and overwhelmed them. In what difmal condition must their planets remain, who have nothing but the dim and twinkling light of the fixed flars to enlighten them ?" Others however, have made suppositions more agreeable to our notions of the benevolent character of the Deity. Sir Isaac Newton thinks that the fudden blaze of some stars may have been occasioned by the falling of a comet

into them, by which means they would be enabled to Conclusions emit a prodigious light for a little time, after which from the they would gradually return to their for the flate. Of foregoing thers have thought that the variable o co, which dif- Appearanappear for a time, were planets, which were only vilible during fome part of their course. But this their apparent immobility, notwithstanding their decrease of luffre, will not allow us to think. Some have imagined, that one fide of them might be naturally much driker than the other, and when by the revolution of the flar upon its axis the dark fide was turned towards us, the star became invisible, and for the same reason, after some interval, resumed its former luttre. Mr Maupertuis, in his differtations on the figures of the Opinion of celestial bodies (p. 61-63.), is of opinion, that some Mi Mauflars by their prodigious quick rotations on their axes, pertuismay not only affine the figures of oblate fpheroids, but that, by the great centrifugal force ariting from fuch rotations they may become of the figures of mill-stones: or be reduced to flat circular planes, so thin as to be quite invisible when their edges are turned towards us; as Sasurn's ring is in fuch politions. But when very eccentric planets or comets go round any flat ftar, in orbits much inclined to its equator, the attraction of the planets or comets in their perihelions must alter the inclination of the axis of this star; on which account it will appear more or less large and luminous, as its broad fide is more or less turned ton wards us. And thus he imagines we may account for the apparent changes of magnitude and luttre in those,

ftars, and likewise for their appearing and disappearing.

Lastly, Mr Dunn (Phil. Trans. Vol. Last.), as a dis-Mr Dunn's fertation concerning the apparent increase of magnitude hypothesis. tude in the heavenly bodies when they approach the horizon, conjectures that the interpolition of long grofs atmosphere may folve the phenomena of new stars. "The phenomena of new stars." bulous and new stars (fays he) have engaged the sttention of curious astronomers; but none that I know of have given any reason for the appearance of nebulous stars. Possibly what has been before advanced may also be applicable for investigating reasons for those strange appearances in the remote parts of the universe. From many inflances which might be produced concerning the nature and properties of lights and illuminations on the earth's furface, concerning the nature and properties of the earth's atmosphere, and concerning the atmospheres and illuminations of comets, we may fafely conclude, that the atmospheres of comets and of our earth are more gross in their nature than the ethereal medium which is generally diffused through the folar fystem. Possibly a more aqueous vapour in the one than the other makes the difference. Now as the atmospheres of comets and of planets in our folar fystem are more gross than the ether which is generally diffuled through our folar fystem, why may not the ethereal medium diffused throughout those other solar fystems (whose centres are their respective fixed stars) bemoregrossthan the ethereal medium diffused throughout our solar system? This indeed is an hypothesis, but fuch a one as agrees exactly with nature. For thefe nebulous stars appear so much like comets, both to the naked eye and through telescopes, that the one cannot always, by any difference of their extraneous light, be known from the other. Such orbs of gross ether re-

Mr Mi-

je**ctures**

ed stars.

Conclusions flecting light more copiously, or like the atmospheres from the of comets, may help us to judge of the magnitudes of Appearunother means feem to fail. The appearance of new stars, and disappearance of others, possibly may be occasioned by the interpolition of fuch an ethereal medium, within their respective orbs, as either admits light to pass freely, or wholly absorbs it at certain times, whilit light is constantly pursuing its journey through the valt

> In the Philosophical Transactions for 1783, however, Mr Michell, in proposing a method to determine

> the distance, magnitude, &c. of the fixed stars by the

regions of space."

diminution of the velocity of their light, should any fuch thing be discovered, makes such suppositions as feem totally inconfistent with what has been just now advanced. "The very great number of flars (fays he) that have been discovered to be double, triple, &c. chell's conparticularly by Mr Herschel, if we apply the doctrine concerning of chances, as I have heretofore done in my Inquiry the nature into the probable parallax, &c. of the fixed stars, pubof the fix- lifted in the Philosophical Transactions for the year 1767, cannot leave a doubt with any one who is properly acquainted with the force of those arguments, that by far the greatest part, if not all of them, are fyftems of flars to near each other, as probably to be liable to be affected fensibly by their mutual gravitation; and it is therefore not unlikely, that the periods of the revolutions of some of these about their principals (the imalier ones being, upon this hypothelis, to be confidered at litellities to the others) may some time or other be discovered. Having then shown in what manuer the magnitude of a fixed flar, if its density were allowed sould affect the velocity of its light, he not like at last, that " If the semidiameter of a sphere of the name dealty with the sun were to exceed his in the proportion of 500 to 1, a body falling from an insuite height towards it (or moving in a parabolic surve at its furface) would have acquired a greater velocity than that of light; and confequently supposing light to be attracted by the same force in proportion to its vis inertia with other bodies, all light emitted

return to the body that emits

midiameters invertely." After proceeding in his calculations, in order to find the diameter and distance of any star, he proceeds thus: " According to Mr Bouguer, the brightness of tive bright the fun exceeds that of a wax candle in no less a proness of the portion than that of 8000 to 1. If therefore the fun and fix-brightness of any of the fixed stars should not exceed that of our common candles, which, as being fomething lefo luminous than wax, we will suppose in round numbers to be only one ten thousandth part as bright as the fun, fuch a fiar would not be visible at more than one hundredth part of the distance at which it would be seen if it were as bright as the sun. Now,

from fuch a body would be made to return towards it

by its own proper gravity. But if the femidiameter

of a sphere, of the same density with the sun, was of

any other fize less than 497 times that of the sun; though the velocity of light emitted by fuch a body

would never be wholy deftroyed, yet it would always

fuffer some diminution, more or less according to the

magnitude of the sphere. The same effects would like-

wife take place if the femidiameters were different

from those aheady mentioned, provided the density

was greater or less in the duplicate ratio of those se-

because the fun would still, I apprehend, appear as Conclusion bright and luminous as the star Sirius, if removed to from the 400,000 times his present distance, such a body, if no foregoing Appearant brighter than our common candles, would only appear equally luminous with that star at 4000 times the distance of the fun; and we might then be able, with the best telescopes, to distinguish some sensible apparent diameter of it: but the apparent diameters of the stars of lesser magnitudes would still be too fmall to be diffinguishable even with our best telescopes, unless they were yet a good deal less luminous; which may possibly, however, be the case with some of them: for though we have indeed very flight grounds to go upon with regard to the specific brightness of the fixed flars, compared with that of the fun at prefent, and can therefore form only very uncertain and random conjectures concerning it; yet from the infinite variety which we find in the works of the creation, it is not unreasonable to suspect, that very possibly some of the fixed flars may have fo little natural brightness in proportion to their magnitude, as to admit of their diameters having some sensible apparent size when they shall come to be more carefully examined, and with larger and better telescopes than have been hitherto in common use.

" With regard to the fun, we know that his whole Luminous furface is extremely luminous, a very small and tem-appearence porary interruption fometimes, from a few spots, ex-of the for cepted. This universal and excessive brightness of the supposed to whole furface is probably owing to an atmosphere, from an which being luminous throughout, and in some mea-atmosfure also transparent, the light proceeding from a con-phere. siderable depth of it all arrives at the eye, in the same manner as the light of a great number of candles would do if they were placed one behind another, and their flames were fufficiently transparent to permit the light of the more distant ones to pass through those

that were nearer without interruption.

" How far the same constitution may take place in the fixed flars we do not know: probably, however, it may faill do fo in many; but there are fome appearances, with regard to a few of them, which feem to make it probable that it does not fo univerfally. Now, if I am right in supposing the light of the sun to proceed from a luminous atmosphere which must necessarily diffuse itself equally over the whole surface, and I think there can be very little doubt that this is really the case, this constitution cannot well take place in those stars which are in some degree periodically more and less luminous, such as that in Collo Ceti, &c. It is also not very improbable, that there is some Of the vadifference from that of the fun in the constitution of riable stars. those stars which have sometimes appeared and disappeared, of which that in the confellation of Cassiopeia is a notable instance. And if these conjectures are well founded which have been formed by fome philofophers concerning flurs of this kind, that they are not wholly luminous, or at least not constantly for but that all, or by far the greatest part of their furfaces, is subject to considerable changes, sometimes becoming luminous, at others extinguished; it is amongst stars of this fort that we are most likely to meet with instances of a sensible apparent diameter, their light being much more likely not to be fo great in proportion as that of the fun, which if removed to 400,000 times his present distance, would still appear,

Compara-

Copclusions I apprehend, as bright as Sirins, as I have observed from the above; whereas it is hardly to be expected, with any telefcope whatfoever, that we flould ever be able to distinguish a well-defined disk of any body of the same fize with the fun at much more than 10,000 times his prefert diffance.

" Hence the greatest distance at which it would be possible to diffinguish any fensible apparent diameter of a body as denfe as the fun, cannot well greatly exceed five hundred times ten thousand; that is, five million times the distance of the sun; for if the diameter of fuch a body was not less than 500 times that of the fun, its light, as has been shown above, could never arrive at us."

202 Mr Hershel's opiwon con-

Mr Herschel, improving on Mr Michell's idea of the fixed stars being collected into groups, and alstrong the fifted by his own observations with the extraordinary telescopic powers already mentioned, has suggested a tion of the theory concerning the construction of the universe entirely new and fingular. It had been the opinion of former astronomers, that our fun, besides occupying the centre of the fyllem which properly belongs to him, occupied also the centre of the universe; but Mr Herschel is of a very different opinion. " Hitherto (fays he) the fidercal heavens have, not inadequately for the purpose designed, been represented by the concave furface of a sphere, in the centre of which the eye of the observer might be supposed to be placed. It is time, the various magnitudes of the fixed flars even then plainly fuggefied to us, and would have better furted, the idea of an expanded firmament of three dimensions; but the observations upon which I am now going to enter, still farther illustrate and enforce the necessity of confidering the heavens in this point of view. In future therefore we shall look upon those regions into which we may now penetrate by means of fuch large telefcopes, (A) as a naturalist regards a rich extent of ground or chain of mountains. containing firata variously inclined and directed, as well as confishing of very different materials. A furface of a globe or map therefore will but ill delineate the interior parts of the heavens."

201 His observations on the V12 Lactea.

With the powerful telescope mentioned in the note, Mr Herschel first began to survey the Via Lactea, and found that it completely resolved the whitish appearance into flars, which the telescopes he formerly used had not light enough to do. The portion he first obferved was that about the hand and club of Orion; and found therein an aftonishing multitude of stars, whose number he endeavoured to estimate by counting many fields (n), and computing from a mean of these how many might be contained in a given portion of the milky-way. In the most vacant place to be met with in that neighbourhood he found 63 ftars; other fix fields contained 110, 60, 70, 90, 70, and 74 stars; a mean of all which gave 79 for the number of stars to each field: and thus he found, that by allowing 15 minutes for the diameter of his field of view, a helt of 15 degrees long and two broad, which he had often

seen pass before his telescope in an hour's time, could Conclusions not contain less than 50,000 flars, large enough to be from the diffinctly numbered; besides which, he suspected twice foregoing Appearanby faint glimples for want of sufficient light.

The fuccef, he had with the milky-way foon induced him to turn his telescope to the nebulous parts of the On the heavens, of which an accurate lift had been published nebulæ. in the Connoissance des Temps for 1783 and 1784. Most of these yielded to a Newtonian resector of 20 feet focal distance and 12 inches aperture; which plainly discovered them to be composed of stars, or at least to contain flars, and to show every other indication of consisting of them entirely "The nebulæ (says he) They urs are arranged into ftrata, and run on to a great length; arranged and some of them I have been able to pursue, and to into itrata, guels pretty well at their form and direction. It is probable enough that they may furround the whole flarry sphere of the heavens, not unlike the milky-way, which undoubtedly is nothing but a firstum of fixed flars: And as this latter immense flarry bed is not of equal breadth or fuffre in every part, nor runs on in die firaight direction, but is curved, and even divided into two fireams along a very confiderable portion of it; we may likewife expect the greatest variety in the ftrata of the ciphers of ftars and nebulm. One of thefe firsts of the clusters of stars and nebules. One of these nebulous beds is so rich, that, in pulling through a section of it in the time of only 46 menutes. I have detected no less than 31 nebules, all districtly visible upon a fine blue sky. Their states and start, as well as condition, seem to dequae the granted rester, imaginable. In another stratum, as without rester to tranch of the fornier, I have notice stratum treble nebule variously arranged; later the stratum of the stratum, in the stratum of the contest of time of the stratum of the contest of time. With a seeming attended to others of the cometic flame, with a feeming audiest in the centre, or like cloudy thers, furrounded with a nebulous atmosphere : a different fort again contain a nebulofity of the milky kind, like that wonderful inexplicable phenomenon about & Orionis; while others shine with a fainter mottled kind of light, which de-

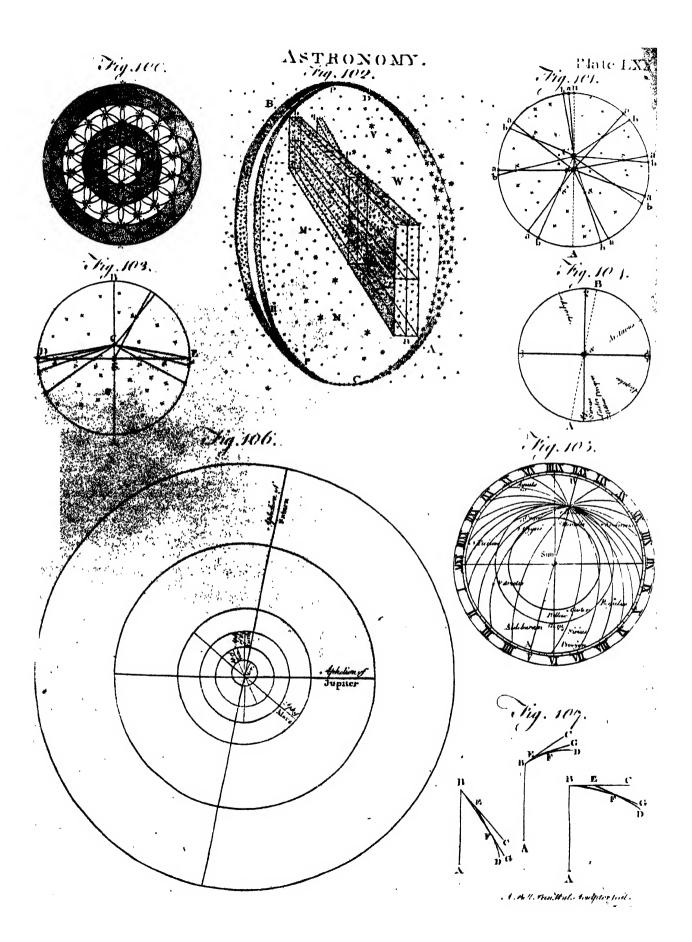

"It is very probable that the great stratum called why the the milky-way, is that in which the fun is placed, though milky-way perhaps not in the very centre of its thickness. We appears to gather this from the appearance of the galaxy, which furround feems to encompais the whole heavens, as it certainly must do if the sun is within the same. For suppose a number of stars arranged between two parallel planes, indefinitely extended every way, but at a given confiderable distance from one another, and calling this a fidereal flutum, an eye placed fomewhere within it will see all the stars in the direction of the planes of the stratum projected into a great circle, which will appear lucid on account of the accumulation of the flars, while the rest of the heavens at the sides will only seem to be scattered over with constellations, more or

notes their being refolvable into stars.

lefs

(A) Mr Herschel's observations, on which this theory is founded, were made with a Newtonian reslector of so feet focal length, and an aperture of 18 inches.

(a) By this word we are to understand the apparent space in the heavens he could see at once through his telefcope.

Ct B.

Conclusions less crowded according to the distance of the planes or from the number of stars contained in the thickness or sides of foregoing the firatum. Appearan-

"Thus in fig. 102. an eye at S within the stratum a b, will fee the stars in the direction of its length a b, or height e d, with all those in the intermediate situation, projected in the lucid circle ABCD; while those in the sides me, new, will be seen scattered over the remaining part of the heavens at MVNW.

208 Celcitial appearances folved on Mr Herschel's hypothefis.

" If the eye were placed fomewhere without the stratum, at no very great distance, the appearance of the flars within it would affume the form of one of the leffer circles of the sphere, which would be more or less contracted to the distance of the eye; and if this distance were exceedingly increased, the whole stratum might at last be drawn together into a lucid spot of any shape, according to the position, length, and height of the firatum.

"Let us now suppose, that a branch or smaller firetum should run out from the former in a certain direction, and let it also be contained between two parallel planes extended indefinitely opwards, but to that the eye may be placed in the great fratum fomewhere before the leparation, and not far from the place where the firsts are full united; then will this second firstum not be projected into a bright eircle like the former, but will be feen as a lucid branch proceeding from the first, and setuming to it again at a certain distance less than a semicircle. Thus in the same figure, the stars in the small seminary a will be projected into a bright web at PRRP, blick, after its separation from the charle CBD, united with it again at P.

What has been instanced in parallel planes may

sally be special to firsts irregularly bounded, and many me appared to strain avegularly bounded, and comming to various discriming to the unantities of the printings to the distance of the eye than the distance of the eye

aco in the projections.

Of the lin's "From appearances, then, as I observed before, we place in the may infer, that the fun is most likely placed in one of the great firsts of the fixed flars, and very probably not far from the place where some smaller firatum branches out from it. Such a supposition will satisfactorily, and with great simplicity, account for all the phenomena of the milky way; which, according to this hypothesis, is no other than the appearance of the projection of the stars contained in this stratum and its secondary branch. As a farther inducement to look on the galaxy in this point of view, let it be confidered, that we can no longer doubt of its whitish appearance arising from the mixed lustre of the numberless flars that compose it. Now, should we suppose it to be an irregular ring of stars, in the centre nearly of which we must then suppose the sun to be placed, it will appear not a little extraordinary, that the fun, being a fixed flar, like those which compose this imagined ring, should just be in the centre of such a multitude of celestial bodies, without any apparent reason for this fingular diffinction; whereas, on our fuppofition, every flar in this stratum, not very near the termination of its length or height, will be so placed as also to have its own galaxy, with only such variations Vol. Il. Part II.

in the form and luftre of it as may arise from the par-Conclusion ticular fituation of each flar.

" Various methods may be taken to come to a Appear knowledge of the fun's place in the fidereal ftratum, one of which I have already begun to put in practice : I call it gauging the beavens, or the star-gauge. confifts in repeatedly taking the number of stars in ten Herschel's fields of view of my reflector very near each other; and method of by adding their fums, and cutting off one decimal on sanging the right, a mean of the contents of the heavens in all the parts which are thus gauged is obtained. Thus it appears that the number of stars increases very much as we approach the milky way; for in the parallel from 92 to 94 degrees north polar diffance, and right afcention 15h. 10, the flar gauge runs up from 9.4 stars in the field to 18.6 in about an hour and a half; whereas in the parallel from 78 to 80 degrees north polar distance, and R. A. 11, 12, 13, and 14 hours, it very seldom rises above 4. We are, however, to remember, that, with different instruments, the account of the gauges will be very different, especially on our supposition of the sun in a stratum of stars. For let a b, fig. 98. be the stratum, and suppose the small circle g b l k to represent the space into which, by the light and power of a given telescope, we are enabled to penetrate, and let GHLK be the extent of another portion which we are enabled to vifit by means of a larger aperture and power; it is evident, that the gauges with the latter instrument will differ very much in their account of stars contained at MN and at KG or LH, when with the former they will hardly be affected with the change from m n to k g or l k.

"The situation of the sun in the sidereal stratum How to will be found by confidering in what manner the flar-find the gauge agrees with the length of a ray revolving in ferium in the veral directions about an assumed point, and cut offsidereal by the bounds of the ftratum. Thus, in fig. 99. let S ftratum. be the place of an observer; Srrr, Srrr, lines in the planer Sr, r Sr, drawn from S within the stratum to one of the boundaries here represented by the plane AB. Then, fince neither the fituation of S nor the form of the limiting Inrface A B is known, we are to affume a point, and apply to it lines proportional to the feveral gauges that have been obtained, and at fuch angles from each other as they may point out: then will the termination of these lines delineate the boundary of the firatum, and confequently manifest the situation of the

fun within the same.

"In my late observations on nebulæ, I soon found, Observathat I generally detected them in certain directions ra-tions on ther than in others: that the spaces preceding them nchulæ. were generally quite deprived of their flars, fo as often to afford many fields without a fingle flar in it: that the nebulæ generally appeared fome time after among flars of a certain confiderable fize, and but seldom among very small stars: that when I came to one nebule, I generally found several more in the neighbourhood: that afterwards a confiderable time paffed before I came to another parcel. These events being often repeated in different altitudes of my inftrument, and some of them at considerable distances from each other, it occurred to me that the intermediate spaces between the sweeps might also contain nebulæ; and finding this to hold good more than once, I ventured to give

flow notice to my affiftant at the clock, that ' I found myflances of vacant places preceding and following the nebulous strata, and their being as it were contained in a bed of flars sparingly scattered between them, may hold good in more diffant portions of the heavens, and which I have not yet been able to vifit in any regular manner, I ought by no means to hazard a conjecture. I may venture, however, to add a few particulars about the of the direction of some of the capital strata or their princi- branches. The well known nebula of Cancer, visible to the nuked eye, is probably one belonging to a certain stratum, in which I suppose it to be so placed as to lie nearest to us. This stratum I shall call that of Cancer. It runs from a Cancri towards the fouth, over the 67th nebula of the Connoissance des Temps, which is a very beautiful and pretty much compressed cluster of stars, easily to be seen by any good telescope; and in which I have observed above 200 stars at once in the field of view of my great reflector with a power of 157. This clufter appearing so plainly with any good common telescope, and being so near to the one which may be feen with the naked eve, denotes it to he probably the next in distance to that within the quartile formed by 2. d, n, s. From the 67th nebula the itratum of Cancer proceeds towards the head of Hydra: but I have not yet had time to trace it farther than the "quator.

" Another flratum, which perhaps approaches nearer to the foler fystem than any of the rest, and whose situation is nearly at rectangles with the great fidereal stratum in which the fun is placed, is that of Coma Berenices, as I shall call it. I suppose the Coma itfelf to be one of the cluffers in it, and that on account of its nearness it appears to be so scattered. It has many capital nebulæ very near it: and in all probability this itratum runs out a very confiderable way. It may perhaps even make the circuit of the heavens, though very likely not in one of the great circles of the fphere; for unless it should chance to intersect the great fidereal stratum of the milky way before mentioned, in the very place in which the fun is stationed, fuch an appearance would hardly be produced. However, if the stratum of Coma Berenices should extend fo far as I apprehend it may, the direction of it towards the north lies probably, with fome windings, through the Great Bear onwards to Cassiopeia, thence through the Girdle of Andronieda and the Northern Fish, proceeding towards Cetus; while towards the fouth it passes through the Virgin, probably on to the tail of Hydra and Centaurus."

became confirmed in his notions; and in a fucceeding paper * has given a tketch of his opinions concerning the interior construction of the heavens .- " That the milky way (fays he) is a most extensive stratum of the of various fizes, admits no longer of the leaft whilet; and that our fun is one of the heavenly bodies ior con- selonging to it is as evident. I have now viewed and retign of sugged this finning zone in almost every direction, and composed of shining stars, whose number, by count of those gauges, contantly increases and fee in proportion to its apparent brightness to

By a continued feries of observations, Mr Herschel

the ked eye. But in order to develope the ideas of the werfe that have been fuggeiled by my late obfervations, it will be best to take the subject from a Conclusions point of view at a confiderable diffance both of space from the foregoing and time.

"Let us then suppose numberless stars of various Appearanfizes feattered over an indefinite portion of space, in fuch a manner as to be almost equally distributed thro' the whole. The laws of attraction, which no doubt Confequenextend to the remotest regions of the fixed stars, will eer of the extend to the remotelt regions of the fixed mais, win lows of atoperate in fuch a manner as most probably to produce traction acthe following remarkable effects.

" I. It will frequently happen, that a ftar, being the ftars, confiderably larger than its neighbouring ones, will attract them more than they will be attracted by Nebula, others that are immediately around them; by which how formmeans they will be in time, as it were, condenfed about ed. a centre; or, in other words, form themselves into a cluster of stars of almost a globular figure, more or less regularly so according to the fize and original distance of the furrounding stars. The perturbations of thefe mutual attractions must undoubtedly be very intricate, as we may cally comprehend, by confidering what Sir Isaac Newton has said, Princip. lib. i. prop. 38. et feq.: but in order to apply this great author's reasoning of bodies moving in ellipses to such as are here for a while supposed to have no other motion than what their mutual gravity has imparted to them, we must suppose the conjugate axes of these ellipses indefinitely diminished, whereby the ellipses will become straight lines.

"II. The next case, which will happen almost as frequently as the former, is where a few flare, thempth not superior in fize to the reft, may chance to be ther nearer each other than the furroundiar ones of for here also will be formed a prevailing attraction in the combined centre of gravity of them all, which will be casion the neighbouring stars to draw together; mint, indeed, fo as to form a regular globular figure, but however, in fuch a manner as to be condensed rowards the common centre of gravity of the whole irregular cluster. And this construction admits of the utmost variety of shapes, according to the number and situation of the flars which first gave rife to the condensation of the reft.

** III. From the composition and repeated conjunction of both the foregoing forms, a third may be derived, when many large stars, or combined small ones, are fituated in long extended regular or crooked rows, hooks, or branches; for they will also draw the furrounding ones fo as to produce figures of condenfed flars coarfely fimilar to the former, which gave rife to thefe condensations.

" IV. We may likewise admit of still more extenfive combinations; when, at the same time that a clufter of flars is forming in one part of space, there may be another collecting in a different, but perhaps not far diffant, quarter, which may occasion a mutual approach towards their common centre of gravity.

V. In the last place, as a natural confequence of Vacancies, the former cases, there will be great cavities or vacan-how they cies formed by the retreat of the stars towards the va-are occarious centres which attract them; fo that, upon the fioned in whole, there is evidently a field of the greatest variety he heafor the mutual and combined attractions of the heaven-vens ly bodies to exert themselves in.

" From this theoretical view of the heavens, which

Will.f arfus. ٠X٧. 214 the m213

218 How the fter, muft at pear to ns accord

Conclusions has been taken from a point not less distant in time from the than in space, we will now retreat to our own refined for Let B flation, in one of the planets attending a flar in its great combination with numberless others, and in order to investigate what will be the appearances from this contricted fituition, let us begin with the naked eye. The flars of the first magnitude, being in all probibility then arefl, will furnish us with a step to begin our leale. Setting off, therefore, with the diffance of Sims or Aichain, for inflince, as unity, we will hypothelis at prefent suppose, that those of the second magnitude are at double, those of the third at treble, the distance, &c Taking it for granted, then, that a ftar of the fevent's magnitude (the finallest supposed visible with the niked eye) is about feven times as far as one of the first, it follows, that an observer who is enclosed in a globular clutter of thats, and not far from the centre, will never be able with the naked eye to fee to the end of it, for fince, according to the above estimations, he can only extend his view to above feven times the diffance of Sirius, it cannot be expected that his eyes should reach the borders of a cluster which has perhaps not less than 50 stars in depth everywhere around him. The whole universe to him, therefore, will be comprised in a fet of confiellations righly ornamented with scattered flars of all sizes: Oi, if the united brightness of a neighbouring cluster of stars should, in a remarkable clear night, reach his fight, it will put on the appearance of a small, faint, whitish nebulous cloud, not to be perceived without the greatest attention. Let us suppose him placed in a much extended firstum, or branching cluster of millions of stars, such as may fall under the third form of nebulæ already confidered. Here also the heavens will not only be nichly scattered over with brilliant constellations, but a shining zone or milky way will be perceived to furround the whole sphere of the heavens, owing to the combined light of those stars which are too small, that is, too remote to be feen. Our observer's fight will be so confined, that he will imagine this fingle collection of flars, though he does not even perceive the thousandth part of them, to be the whole contents of the heavens. Allowing him now the use of a common telescope, he begins to suspect that all the milkiness of the bright pith which furrounds the sphere may be owing to flars. He perceives a few clusters of them in various parts of the heavens, and finds also that there are a kind of nebulous patches. but still his views are not extended to reach to far as to the end of the stratum in which he is fituated, fo that he looks upon these pitches as belonging to that lystem which to him seems to comprehend every celestial object. He now increates his power of vision, and applying himself to a close observation, finds that the milky way is indeed no other than a collection of very small flars. He perceives, that those objects which had been called nelule, are evidently nothing but lufters of ft rs. Then number increases upon him, ud when he refolves one nebula into stars, he discovers ten new ones which he cannot refolve. He then forms the idea of immense strata of fixed stars, of cluster of this and of nebula, till, going on with fuch interefting observations, he now perceives, that all thefe appenances must naturally arise from the confined sit intion in which

we are placed. Confined it may justly be called, though consider m no less a space than what appeared before to be the from foregu whole region of the fixed flars, but which now has af fumed the shape of a crookedly branching nebula, not indeed in one of the leaft, but perhaps very for fom being the most considerable, of those numberless clusters that enter into the construction of the heave is."

Our author now proceeds to show that this theoretical in fivour Our author now proceeds to show in a trus theoretic a view of the heavens is perfectly confident with facts, to ng the and feems to be confirmed by a fires of observations ry from ... Many hundreds of nebula of the first and second form fivitions are to be feen in the heavens, and their places, he fays, in nebular will hereafter be pointed out, many of the third form described, and inflances of the fourth related, a few of the cavities mentioned in the fifth particular z d, though many more have been already observed to that, "upon the whole (trys he), I believe it will bfound that the foregoing theoretical view, with all its confequential appearances, as feen by an eye enclosed in one of the nebula, is no other than a drawing frem nature, wherein the features of the on mil his been closely copied and I hope the retemblance will not be called a bid one, when it shall be considered how vir limited mult be the pencil of in inhabit int of fo in ill and retired a portion of an indefinite faltem in attempting the picture of to unbounded an extent "

Mi Herichel next prefents us with a long table of Method of flat ganges, or accounts of the numbers of flars at once nealming in the field of his telescope, which go a high a 588, the dinienafter which he propoles the following

PROBIEM.

"The stars being supposed nearly equally scattered, and their numb i, is a field for wof a known ingu las diameter, being given, to d termine the length of the vifudity

" Here, the arrangement of the flar not being fix ed upon, we must endersou to find which way they may be placed to as to fill a given force most equally Suppose a rectangular cone cut into trudula ly mary equidiftant planes perpendicular to the axis, then, i one star be placed it the vertex and mother in the xi at the first interfection, his star may be fet around it is as to be equally diffant from one another and from the central flar. These positions being carried on in the fame manner, we shall have every it is within the cone furrounded by eight others at in equal diffrace from that star tiken as a centre I g. 100 contains some fections of fuch a cone distinguished by alternate shades, which will be fufficient to explain what fort of an ingment I would point out.

"The feries of the number of flir contained in the several sections will be 1, 7, 19, 37, 61, 91, 8c which, continued to n terms, the fum of it, by the differential method, will be $na + n = \frac{n-1}{2} d + n = \frac{r-1}{2}$

 $\frac{n-2}{3}d^n$, &c. where a is the first term, d, d', d', &c. the first, second, and third differencer Then, fince a= 1, d=6, d=6, d''=0, the fum of the ferres will be n^3 . I ct 5 be the given number of flurs; I the diameter of the bale of the held or view, and B the diameter of the giest rectangular cone, and by trigonometry we shall oregoing

221 Epols of

222

Radius om the have B= Radius
Tang. 'f field' Now, fince the field of view

stran- of a telescope is a cone, we shall have its solidity to that of the great cone of the flars formed by the above conftruction, as the fquare of the diameter of the base of the field of view, to the square of the diameter of the great cone, the height of both being the fame; and the stars in each cone being in the ratio of the fo-

Indity, as being equally feathered, we have n= AB'S; and the length of the vifual ray =n-1, which was to be determined." Another folution of this problem on the supposition of another arrangement of stars, is

given; but Mr Herschel prefers the former.

From the data now laid down, Mr Herschel next fidercal endeavours to prove that the earth is the planet of kem be- a ftar belonging to a compound nebula of the third a nebu-form.' "I shall now (fays he) proceed to show, that the flupendous fidereal fystem we inhabit, this extensive fliatum, and its secondary branch, confishing of many millions of stars, is in all probability a detached nebula-In order to go upon grounds that frem to me to be capuble of great certainty, they being no lefs than an actual furvey of the boundaries of our indereal fystem, which I have plainly perceived as far as I have yet gone round it, everywhere terminated, and in most places very narrowly too, it will be proper to flow the length of my founding line, if I may to call it, that it may appear whether it was fufficiently long for the purpofe.

ength of " In the most crowded parts of the milky way, 1 e line by, have had fields of view that contained no fewer than hich Mr 588 state, and these were continued for many minutes: fo that in one quarter of an hour's time there cheavers passed no less than 116,000 flars through the field of view of my telescope. Now, if we compute the length of the vitual ray, by putting S=588, and the diameter of the field of view 15 minutes, we shall find

> n=1 B'S=498; fo that it appears the length of what I have called my founding line, or n-1, was not probably less than 497 times the distance of Sirius f.on the fun.

> "It may feem inaccurate that we should found an argument on the flars being equally feattered, when, in all probability, there may not be any two of them in the heavens whose mutual distance shall be equal to that of any other two given stars: but it should be confidered, that when we take all the flars collectively, there will be a mean distance which may be assumed as the general one; and an argument founded on such a supposition will have in its favour the greatest probability of not being far short of truth. And here I must observe, that the difference between a crowded place and a cluster (none of the latter being put into the gauge table), may eafily be perceived by the arrangement as well as the fize and mutual diffance of the stars; for in a cluster they are generally not only refembling each other pretty nearly in fize, but a certain uniformity of diffance also takes place: they are more and more accumulated towards the centre, and put on all the appearances which we should naturally expect from a number of them collected into a group at a certain distance from us. On the other hand, the rich parts of the milky way, as well as those in the distant

broad parts of the firstum, confift of a mixture of flars Conclusions of all possible fires, that are seemingly placed without from the any purticular apparent order. Perhaps we might re- foregoing Appearcollect, that a greater condensation towards the centre of our fythem than towards the borders of it should be taken into confideration; but with a nebula of the third form, containing fuch various and extensive combinations as I have found to take place in ours, this circumstance, which in one of the first form would be of confiderable moment, may, I think, be fately neglected.

" If some other high gauge be selected from the

table, such as 472 or 344, the length of the visual ray

will be found 461 and 415. And although, in confe-

quence of what has been faid, a certain degree of

doubt may be left about the arrangement and leatter

ing of the stars, yet when it is recollected, that in those parts of the milky way, where thefe high gauges were

taken, the stars were neither so small nor so crowded

as they must have been, on a supposition of a much

farther continuance of them, when certainly a milky

or nebulous appearance must have come on, I need

not fear to have overrated the extent of my visual ray;

and indeed every thing that can be faid to shorten it

the diffence of Siring; and the fame telescope which

could flow 588 flars in a field of view of ty minutes,

must certainly have presented me also with the stare in

these fituations, had they been there. If we thould,

answer this by observing, that they might be at too

great a distance to be perceived, it will be allowing

that there must at least be a vacancy amounting to the

length of a vifual ray, not thort of 400 times the di-

not be confident confidently to affirm that we were on

an island, unless we had found ourselves everywhere

bounded by the ocean; and therefore I shall go no far-

ther than the gauges will authorize; but confidering

the little depth of the firstum in all those places which

have been actually ganged, to which must be added all

the intermediate parts that have been viewed and found

to be much like the reft, there is but little room to ex-

pect a connexion between our nebula and any of the

neighbouring ones. A telescope, with a much larger

aperture than my present one, grasping together a

greater quantity of light, and thereby enabling us to

fee farther into space, will be the furest means of com-

pleting and establishing the arguments that have been

used: for if our nebula is not absolutely a detached

one, I am firmly perfuaded that an inflrument may be

made large enough to discover the places where the

fity must there undoubtedly come on, fince the stars in

a field of view will increase in the ratio of n3 greater

than that of the cube of the vifual ray. Thus, if 588

flars in a given field of view are to be feen by a ray of

407 times the distance of Sams, when this is length-

cued to roce, which is but little more than double the

former, the number of stars in the same field of view

ftars continue onwards. A very bright milky nebulo-

flance of Sirius; and this is amply fufficient to make' our nebula a detached one. It is true, that it would

will only contract the limits of our mebula, as it has in most places been of sufficient length to go far beyond the bounds of it. Thus in the sides of our stratum, opposite to our fituation in it, where the gauges often Extent of run below c, our sebula cannot extend to 100 times our nebula.

223 lufter of , ars deıcd.

Appearan-

CCS.

Conclusions will be no less than 4774; for when the visual ray r is

foregoing given, the number of stars S will be $=\frac{\pi 3}{B^3}$; where

n=r+1; and a telescope with a threefold power of extending into space, or with a ray of 1500, which I think may easily be constructed, will give us 16,096 flars. Nor would these be so close, but that a good power applied to fuch an inflrument might eafily diflinguish them; for they need not, if arranged in regular squares, approach nearer to each other than 6".27; but the milky nebulofity I have mentioned, would be produced by the numberless stars beyond them, which, in one respect, the visual ray might also be faid to reach. To make this appear, we must return to the naked eye; which, as we have before estimated, can only see the flars of the seventh magnitude fo as to diffinguish them: but it is nevertheless very evident, that the united luftre of millions of stars, fuch as I suppose the nebula in Andromeda to be, will reach our fight in the shape of a very small faint nebulofity; fince the nebula of which I speak may easily be seen in a fine evening. In the same manner, my present telescope, as I have argued, has not only a visual ray that will reach the stars at 407 times the diffance of Sirius, fo as to diffinguish them, and probably much farther, but also a power of showing the united luftre of the accumulated stars that compose a milky nebulofity at a diffance far exceeding the former limits: so that from these considerations it appears again highly probable; that my prefent telescope not showing fuch a nebulofity in the milky way, goes already far beyond its extent ; and confequently much more would an inftrument, such as I have mentioned, remove all doubt on the subject, both by showing the flure in the continuation of the firatum, and by expofing a very firong milky nebulofity beyond them, that could no longer be mistaken for the dark ground of

Analogical his dactrine.

"To these arguments, which rest on the firm basis arguments of a ferice of observation, we may add the following confiderations drawn from analogy. Among the great number of nebulæ which I have now already feen, amounting to more than 900, there are many which in all probability are equally extensive with that which we inhabit; and yet they are all separated from each other by very confiderable intervals. Some, indeed, there are that feem to be double and treble; and though with most of these it may be that they are at a very great distance from each other, yet we allow that some such conjunctions really are to be found; nor is this what we mean to exclude: But then these compound, or double nebulæ, which are those of the third and fourth forms, still make a detached link in the great chain. It is also to be supposed, that there may be fome thinly scattered solitary stars bet ween the large interflices of nebulæ; which being fituated fo as to be nearly equally attracted by the feveral clufters when they were forming, remain unaffociated; and though we cannot expect to fee those stars on account of their wast distance, yet we may well presume that their number cannot be very confiderable in comparison to those that are already drawn into fystems; which conjecture is also abundantly confirmed in fituations where the nebulæ are near enough to have their stars visible; for they are all infulated, and generally to be feen upon a

very clear and pure ground, without any flar near them Conclude that might be thought to belong to them. And though I have often feen them in beds of stars, yet from the foregoing fize of these latter we may be certain, that they were much nearest a weather than they were the start of the much nearer to us than these nebulæ, and belonged

undoubtedly to our own fyslem."

Having thus determined that the visible system of nature, by us called the universe, confisting of all the celeftial bodies, and many more than can be feen by the naked eye, is only a group of stars or funs with their planets, constituting one of those patches called a nebula, and perhaps not one ten thousandth part of what is really the universe, Mr Herschel goes on to delineate the figure of this vail nebula, which he is of opinion may now be done; and for this purpose he How the gives a table, calculating the distance of the stars which signre of form its extreme boundaries, or the length of the vi-our nebula fual ray in different parts, by the number of flars con-ineated. tained in the field of his telefcope at different times, according to the principles already laid down. He does not, however, as yet attempt the whole nebula, but of a particular fection, represented fig. 160. "1 have taken one (fays he) which paffes through the poles of our fystem, and is at rectangles to the conjunction of its branches, which I have called its length. The name of poles feem to me not improperly applied to those points which are 90 degrees distant from a circle paffing along the milky way; and the north pole is here supposed to be fituated in right ascention 1860, and polar distance (that is from the pole commonly fo called) 58°. The fection is one which makes an angle of 35 degrees with our equator, croffing it in 124; and 304; degrees. A celestial globe, adjusted to the latitude of 55° north, and having o Ceti near the meridian, will have the plane of this fection pointed out by the horizon. The vifual rays are to be projected on the plane of the horizon of the latitude just mentioned, which may be done accurately enough by a globe adjusted in the manner directed. The stars in the border, which are marked larger than the reft, are those pointed out by the gauges. The intermediate parts are filled up by fmaller stars, arranged in straight lines between the gauged ones. From this figure, which I hope is not a very maccurate one, we may fee that our nebula, as we observed before, is of the third form; that is, a very extensive, branching, compound congeries of many millions of stars, which most probably owes its origin to many remarkably large, as well as pretty closely feattered fmall stars, that may have drawn together the rest. Now, to have some idea of the wonderful extent of this fystem, I must observe, that this fection of it is drawn upon a scale where the distance of Sirius is no more than the Soth part of an inch; fo that probably all the stars, which in the finest nights we are able to diffinguish with the naked eye, may be comprehended within a fphere drawn round the large star near the middle, representing our situation in the nebula of less than half a quarter of an inch radius."

Mr Herschel now proceeds to offer some further thoughts on the origin of the nebulous strata of the heavens; in doing which he gives some hints concerning the antiquity of them. " If it were possible (fays he) to diftinguish between the parts of an indefinitely extended whole, the nebula we inhabit might be faid

conclusions to be one that has fewer marks of antiquity than any

127

from the of the rest. To explain this idea perhaps more clear-foregoing ly, we should recollect, that the condensation of clusters of stars has been ascribed to a gradual approach; and whoever reflects on the number of ages that must have paffed before fome of the clusters that are to be found in my intended catalogue of them could be fo far condensed as we find them at present, will not wonder if I ascribe a certain air of youth and vigour to many very regularly feattered regions of our fidereal ftratum. of the de- There are, moreover, many places in it in which, if we ay and re-may judge from appearances, there is the greatest rea-composition fon to believe that the stars are drawing towards secondary centres, and will in time separate into clusters, so as to occasion many subdivisions. Hence we may furmife, that when a nebulous stratum confiles chiefly of nebulæ of the first and fecond forms, it probably owes its origin to what may be called the decay of a great compound nebula of the third form; and that the fubdivitions which happened to it in length of time, occafioned all the small nebulæ which sprung from it to lie in a certain range, according as they were detached from the primary one. In like manner, our fystem, after numbers of ages, may very possibly become divided, fo as to give rife to a stratum of two or three hundred nebulæ; for it would not be difficult to point out to many beginning or gathering chilters in it. This throws a confiderable light upon that remarkable collection of many hundreds of nebulæ which are to be feen in what I have called the nebulous firgium in Coma Berenices. It appears from the extended and branching figure of our nebula, that there is room for the decomposed small nebulæ of a large reduced former great one to approach nearer to us in the fides than in any other parts. Nay, possibly there might originally be another very large joining branch, which in time became separated by the condensation of the stars: and this may be the reason of the little remaining breadth of our fystem in that very place; for the nebulæ of the stratum of the Coma are brightest and most crowded just opposite to our situation, or in the pole of our fythem. As foon as this idea was fuggested, I tried also the opposite pole; where accordingly I have met with a great number of nebulæ, though under a much more scattered form.

" Some parts of our fystem indeed feem already to have fullained greater ravages of time than others; for inflance, in the body of the Scorpion is an opening or hole, which is probably owing to this caufe. It is at least four degrees broad; but its height I have not yet afcertained. It is remarkable, that the 80th Ne'uleuse fans Etoiles of the Connoissance des Temps, which is one of the richest and most compressed clufters of small stars I remember to have seen, is situated just on the west border of it, and would almost authorize a suspicion that the stars of which it is composed were collected from that place, and had left the vacancy. What adds not a little to this furmife is, that the same phenomenon is once more repeated with the Lourth cluster of the Connoissance des Temps; which is also on the western border of another vacancy, and has moreover a fmall miniature cluster, or easily resolvable pebula, of about 2; minutes in diameter north, following it at no very great distance.

"There is a remarkable purity or clearness in the

heavens when we look out of our firatum at the fides; Conclutions that is, towards Leo, Virgo, and Coma Berenices on from the one hand, and towards Cetus on the other; whereas foregoing the ground of the heavens becomes troubled as we approach towards the length or height of it. Thefe troubled appearances are easily to be explained by afcribing them to some of the distant straggling stars that yield hardly light enough to be diffinguished. And I have indeed often experienced this to be the cause, by examining these troubled spots for a long while together, when at last I generally perceived the ftars which occasioned them. But when we look towards the poles of our fystem, where the visual ray does not graze along the fide, the straggling stars will of course be very few in number; and therefore the ground of the heavens will affuine that purity which I have always observed to take place in those regions."

Thue, then, according to Mr Herschel, the universe Universe confilts of nebular or innumerable collections of innu-composed merable flars, each individual of which is a fun not on-of nebule. ly equal, but much superior to ours: at least if the words of Mr Nichollon have any weight; for he tells us, that " each individual fun is destined to give light Nat. Phil. to bundreds of worlds that revolve about it, but which 195, 196 can no more be feen by us, on account of their great distance, than the solar planets can be seen from the fixed flars." "Yet (continues he), as in this unexplored, and perhaps unexplorable, abyte of space, it is no necessary condition that the planets should be of the fame magnitudes as those belonging to our system. it is not impossible but that planetary bodies may be discovered among the double and triple flam.

Though in the above extracts from Mr Merichel's papers, the words condenfacion, clufters, Bee, of fines frequently occur, we are by no means from these to imagine that any of the celefial bodies in our male. are nearer to one another than we are to birius, whole distance is supposed not to be less than accorde times that of the fun from us, or 38 millions of millions of miles. The whole extent of the nebula being in some places near 500 times as great, must be such, that the light of a star placed at its extreme boundary, suppoling it to fly with the velocity of 12 millions of miles every minute, must have taken near 3000 years to reach us. Mr Herschel, however, is by no means of opinion, that our nebula is the most considerable in the universe. " As we are used (says he) to call the appearance of the heavens, where it is furrounded with a bright zone, the milky way, it may not be amiss to point out some other very remarkable nebulæ, which cannot well be lefs, but are probably much larger, than our own fyftem; and being also extended, the inhabitants of the planets that attend the stars which compose them, must likewise perceive the same phenomena: for which reason they may also be called milkyways, by way of diffinction.

" My opinion of their fize is grounded on the fol- of the fize lowing observations: There are many round nebulæ of and dithe first form, of about five or fix minutes in diameter, stance of the flars of which I can fee very diffinetly; and on nebulæ. comparing them with the vifual ray calculated from fome of my long gauges, I suppose by the appearance of the fmall flars in those gauges, that the centres of these round nebulæ may be 600 times the distance of

5 T R 0 N 0 M Y.

Corclusions Strius from us "-He then goes on to tell us, that the from the state in such nebule are probably twice as much contoregoing denfed as those of our fythem; otherwise the centre of it would not be less than 6000 times the distance of Sinus from its, and that it is possibly much underrated by supposing it only 600 times the distance of that fin.

" Some of thele round nebula (fixs Mr Herfehel) have others near them, perfectly limitar in form, coleur, and the diffribution of this, but of only half the dismeter and the flar in then from to be deably crowded, and only at all out half the diffa or from each other. They are inde d fo fmill, as not to be vil ble without the utmost attention. I supp so these ministure nebulæ to be at double the diffance of the first. An instance equally remarkable and a fiructive is a case, where, in the neighbourhood of two fuch nebule as have been mentioned, I met with a third fimilit, refolvable, but much imiller and fainter nebula. The flare of it are no longer to be perceived; but a resemblance of colour with the former two, and its diminished fize and light, may well permit us to place it at full twice the dihance of the fecond, or about four or five times the distance of the first. And yet the nebulosity is not of the milky kind; nor is it to much as difficulty refolvable or colourless. Now in a few of the extendad nebulæ, the light changes gradually, to as from the resolvable to approach to the milky kind; which appears to me an indication, that the milky light of poblic se owing to their much greater differce. A nebelle, energione, where legit is perfectly milky, cannot well be dispensation to at less than fix or eight thousand times the difference of Berius; and though the numbers here allumed are see to be taken otherwise than at many counte eliments, see an extended nebula, which in an oblique fituation, where it is possibly forethortened by one half, two-thirds, or three-fourths of its length, subtends a degree or more in diameter, can-not be otherwise than he wonderful magnitude, and may well outsie our milky-way in grandeur."

Vall length quilite to form the nebales

Mr Herichel next proceeds to give an account of feof time re- veral remarkable nebulso, and then concludes thus: " Now, what great length of time must be required to produce these effects (the formation of nebulae) may easily be conceived, when, in all probability, our whole fyl em of al out 800 stars in diameter, if it were seen at fuch a distance that one end of it might assume the refolvable nebulofity, would not, at the other end, prefent us with the irrefolvable, much less with the colourlels and milky, fort of net ulofitier." Great indeed must be the length of time require for such distant bodies to form combinations by the laws of attraction, fince, according to the diffraces he has als fumed, the light of some of his nebula must be thirtyfic or forty-eight thousand years in arriving from the n to us. It would be worth while then to inquire, whethei attraction is a virtue propagated in time or not; or whether it moves quicker or flower this light?

It the course of Mr Herschel's observations and ina san not quires concerning the flindure of the heavens, an objelion occurred, that if the different fystens were formed by the mutual attractions of the flars, the whole would be in danger of deflication by the falling of them one upon another. A fufficient answer to this, be thinks, is, that if we can really prove the faftem of

the universe to be what he has faid, there is no doubt Conclusion but that the great Author of it has amply provided fire the for the prescrivation of the whole, though it should not appear to us in what manner this is effected. See if circumfi mees, however, he is of opinion, manifefly tend to a general prefervation as, in the fuft place, the indefinite extent of the fidereal heavens, which must produce a balance that will effectually secure all the great parts of the whole from approx ling to each other "There remains then (fixs he) only to fee how the particular stars belonging to deputate chiller are prevented from rufhing on to their centres of a traction." This he supposes may be done by pretile forces; " the admission of which will prove such a burner against the scenning destructive power of attraction, as to fecure it from all the flar belonging to a cluster, it not for ever, at least fer millions of ages. Belides, we ought perhaps to lock upon such challers, and the defirmation of a fter n w aid then in fom thousands of ages, a the very m in by which the whole is preferred and renew 1 I ele clusters may be the laboratories of the univ if, wherein the in it falutary remedies for the decay of the whole are prepared."

In speaking of the planetary nebula by which name Of the planetary he distinguishes those spots that are all over equally lu n tay minous, he fays, "If we should impose them to be nelula". fingle stars with large dismeters, we shall find it diff cult to account for their not being brighter, unless we should admit that the intrinsic light of some it is may be very much inferior to that of the generality, which, however, can hardly be imagined to extend to fuch a degree. We might suppose them to be comet about then aphelion, if the brightness, as well a magnitude of their diameters, did not of pose this idea fo that, after all, we can hardly find any h pothetis fo probable as that of their being nebula , but then they must confift of flars that are compielf d and recumul tel in the highest degree. If it were not perhaps too hazardous to purfue a former furmite of a renewal n what I has a ratively called the Lal natures of the Umverfe, the star forming these extraordinary rebule, by some decry cr walte of nature being no longer ft for their former purpofes, and having their projectile ferces, if an, fuch they had, retuided in each o her's atmosphere, may ruth at last together, and, either in succeision or by one general tremendous shock, unite it to a new body. Perhaps the extraoiding and fud len blize of a new star in Cassiopeia's chai, in 1572, night pilfibly be of fuch a nature. If a little attention to thefe bodies should prove that, having no annual paralliv, they belong most probably to the class of neb ile, they may then be expected to keep their flation better than any one of the flars belonging to our lyttem, on iccount of their being probably at a very gent di-Stance."

Having this at length pot them, he the comp times at the af and theories concerning the acture and litu tions of the face the heavenly bode, we must now proceed to confider flux at 1 those proj the fo ce, which are I profed in chiny to frem the preferention of the lessem of Niene, and to prevent the stars from alm gupon or mother more frequently than they by It was first suspected by Di Halley, that may of the flir which we call find at. really in motion, to rough that motion is or her follow

ibiolute

Benclutions in itself, or the distance is so great, that it can scarce from the be perceptible in half a century. It is, however, now foregoing confirmed by astronomical observations, that Arcturus, Sirius, Aldebaran, Procyon, Castor, Rigel, Altair, and many others, are actually in motion: which confideration, with the length of time necessary to show any change of place, in bodies at fuch extreme distance with the lateness of any observations on this head " would lead us (fays Mr Herschel) to suppose that there is not " one fixed ftar in the heavens;" but " many other reafons (adds he) will render this fo obvious, that there can hardly remain a doubt of the general motion of all the starry systems, and consequently of the solar one among the reft.

Attraction

"I might begin with principles drawn from the theory of attraction, which evidently oppose every idea of abiolute rest in any one of the stars, when once it is known that fome of them are in motion: for the naining at change that must arise by such motion, in the value of a power which acts inverfely as the fquares of the distances, must be felt in all the neighbouring stars; and if thefe be influenced by the motion of the former, they will again affect those that are next to them, and fo on, till all are in motion. Now, as we know feveral stars in divers parts of the heavens do actually change their place, it will follow, that the motion of our tolar fyllem is not a mere hypothesis. And what will give additional weight to this confideration is, that we have the greatest reason to suppose most of those very stars which have been observed to move, to be such

as are nearest to us; and therefore their influence on

After enumerating a great many changes, which,

our fituation would alone prove a powerful argument in favour of the proper motion of the fun, had it been

originally at reft.'

from his own observation, have happened among the erning the fixed flat., and of which we have already given an account, " Does it not feem natural (fays he), that these observations should cause a strong suspicion that most probably every star in the heaven is more or less in motion? And though we have no reason to think that the disappearance of some stars, or new appearance of others, nor indeed that the frequent changes in the magnitude of so many of them, are owing to their change of diffance from us by proper motions, which could not occasion these phenomena without being inconceivably quick; yet we may well suppose, that motion is some way or other concerned in producing these effects. A flow motion, for instance, in an orbit round fome large opaque body, where the flar which is loft or diminished in magnitude might undergo occasional occultations, would account for fome of those changes; while others might perhaps be owing to the periodical return of some large spots on that side of the surface which is alternately turned towards us by the rotatory motion of the star. The idea, also, of a body much flattened by a quick rotation, and having a motion fimilar to the moon's orbit by a change of the place of its nodes, whereby more of the luminous furface would one time be exposed to us than another, tends to the tame end : for we cannot help thinking with M. de la Lande (Mem. 1776), that the same force which gave

fuch rotations would probably also produce motions of

a different kind by a translation of the centre. Now, if

the proper motion of the flars in general be once admit-

ted, who can refuse to allow that our fun with all its Conclusions planets and comets, that is, the folar system, is no lefs from the liable to fuch a general agitation as we find to obtain Appearan-

among the rest of the celestial bodies?

"Admitting this for granted, the greatest difficulty will be how to difcern the proper motion of the fun among to many other and variously compounded motions How to quantity of the supposed proper motion of the sun by a fun. few geometrical deductions; and at the fame time show, by an application of them to some known facts, that we have already some reason to guess which way the

folar fystem is probably tending its course.

" Suppole the fun to be at S, fig. 101. the fixed stars to be dispersed in all possible directions and di-Annees around, at s, s, s, &c. Now, fetting afide the proper motion of the stars, let us first consider what will be the confequence of a proper motion in the fun, and let it move in a direction from A towards B. Suppose it now arrived at C: here, by a mere inspection of the figure, it will be evident, that the stars s, s, s, which were before feen at a a a, will now, by the motion of the fun from S to C, appear to have gone in a contrary direction, and be feen at b b b; that is to fay, every flar will appear more or less to have receded from the point B, in the order of the letters ab. ab. The converse of this proposition is equally true; for if the flare flould all appear to have had a retrogade motion with respect to the point B. it is plain, on a supposition of their being at nest, the fun must have a direct motion thwards the point B. so occasion all these appearances. Erom a doc b ation of what has been faid, we may disw the following inferences:

" 1. The greatest, or total fystematical papellan of the fixed stars (fig. 103.), will fall upon those shift are in the line DE, at rectangles to the direction AB of

the fun's motion.

" 2. The partial systematical parallax of every other far s, s, s, not in the line DE, will be to the total parallax as the fine of the angle BSa, being the fier's diflance from that point towards which the fun moves, to radius.

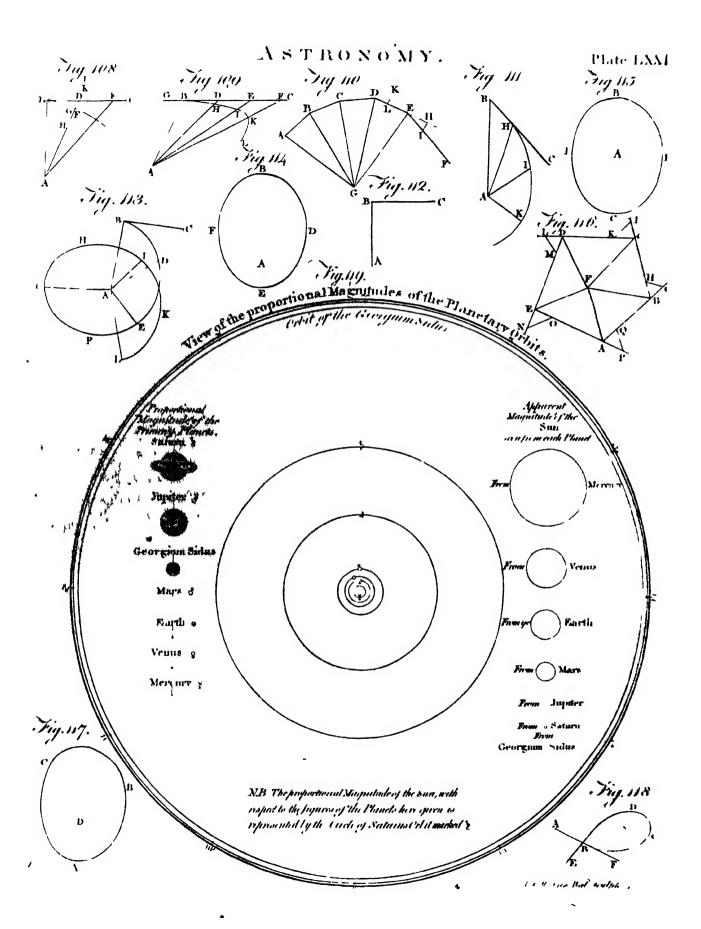

- " 3. The parallax of stars at different distances will be inversely as these distances; that is, one half at double the distance, one third at three times, and so on; for the subtense SC remaining the same, and the parallactic angle being very fmall, we may admit the angle SsC to be inverfely as the fide Ss, which is the flar's distance.
- " 4. Every flar at reft, to a system in motion, will appear to move in a direction contrary to that which the fystem has. Hence it follows, that if the folar fystem be carried towards any star situated in the ecliptic, every flar, whose angular diffance in antecedentia (reckoned upon the ecliptic from the star towards which the fyltem moves) is lefs than 180 degrees, will decrease in longitude; and that on the contrary, every flar, whose distance from the same star (reckoned upon the ecliptic, but in consequentia) is less than 180 degrees, will increase in longitude in both eases, without alteration of latitude.
- "The immense regions of the fixed stars may be confidered as an infinitely expanded globe, having the

of the stars. This is an arduous talk indeed: but I discover the shall point out a method of detecting the direction and proper mo-

ppearance I new .d'15.

lonjec-

Conclusion solar system for its centre. The most p oper method from the therefore of finding out the direction of the motion of foregoing the fun is, to divide our observations on the systema-Appearantical parallax of the fixed state into three principal zones. Thefe, for the corvenience of fixed influment, miy be affunied to as to let them pais around the equator and the folilitial colures, every one being at rectangles to the other two, according to the three dimensions of folds." Our author, then, having informed us that chlervations on double stars are most proper for aftertan my this point, gives an account of three zones he has a tried out for this purpole, the equatorial zone, containing 150 double flars; that of the equinochial colure, extending 10 degrees of a great circle on each tide, as far as it is viable on our hemisphere, which will contain about 70 deble flars; and that of the folfitial coluic, including 120, belides a zone of the ecliptic containing a great many double stars which may undergo occultations by the moon. It is of the fame extent, and includes about 120 double stars.

To apply this theory, it is necessary, in the first place, to observe, that the rules of philosophizing direct ne to refer all phenomena so as few and limple prisciples as are fulficient to explain them. Aftronomers, therefore, having already observed what they call a proper motion in leveral of the fixed flare, and which may be supposed tommon to them all, ought to resolve

may be furplessed equinous to them all, ought to refolve it, as far at possible, into a single and real motion of the loise lyders, is first a fingle and real motion of the loise lyders, is first a fine will answer the known to the proper motion of some last the general law to the proper motions in the loss of the last the proper motions in the loss of and to it, according to their respective right ascensions, having the folar lystem in its centre. Assume the direction AB from a point somewhere not far from the 77th degree of right afcention to its opposite 257th degree, and suppose the sun to move in that direction from S towards B, then will that one motion answer that of all the stars together; for if the supposition be true, Aicturus, Regulus, Pollux, Procyon, Caftor, and Sinns, mould appear to decrease in right ascenfion, while a Aquila, on the contrary, should appear to increale. Moreover, suppose the sun to ascend at the same time, in the same direction, towards some point in the northern hemisplicie, for inflance towards the confiellation Hercules; then will also the observed change of declination of Sinus and Arcturus be refolved into the fingle motion of the fallem. Many difficulties indeed yet remain, such as the correspondence of the exact quantity of notion observed in each flar, with what will be affigued to it by this hypothesis. But it is to be remembered, that the very different and still unknown dilances of the fixed flars must, for a good while yet, leave us in the dark as to the fluct application of the theory; and that any deviation from it may eatily be accounted for from the still unknown real pro er motion of the flars; for if the folar system have Vol. II. Part II.

in reality the motion now afcribed to it, then what al . Conclusion nomers have already observed concerning the change from the of place of the flirs, and have called their proper motion, will become only an apparent motion; and fiture

Apparent motion; observations must still point out, by the deviations from the general law, which the stars will follow in those apparent motions, what may be their real proper motions, as well as relative diffances. " But (fays Mi. Herschel) left I should be censured for admitting fo new and capital a motion upon too flight a found ition, I must observe, that the concurrence of these seven principal stars cannot but give some value to an hypothesis that will simplify the celestial motions in general. We know that the fun, at the distance of a fixed star. would appear like one of them, and from analogy we conclude the fixed flars to be funs. Now, tince the apparent motions of those seven stars may be accounted for, either by supposing them to move in the mariner they appear to do, or elfe by supposing the iun alone to have a motion in a direction for thew not far from that which I have affirmed to it, I think we are 10 more authorized to suppose the fur at rest than we should be to day the diminil motion of the outle, excepting in this sespect, that it proof of the latter to very numerous, wherea the fire relicionly on a few though capital teffimatic

Fig. 105, represents them projected on the plane or the equator. They are all in the northern hemisphe e except Sirius, which mult be supposed to be viewed in the concave part of the opposite half of the globe, while the reft are drawn on the convex furface. Regulus being added to that number, and Cattor being double, we have 14 flars; and every ft n's motion except Regulus being affigued in declination as well as right afcention, we have no fewer than 27 given motions to account for. Now, by assuming a point some- Motions of where near A Hercules, and supposing the fun to have the stars a proper motion towards that part of the heavens, we recounted shall account for 22 of these motions. In & Cygn, for. * Aquilæ, & Cygni, y Pifeium, y Arietis, and Aldebaran, ought, upon the supposed mot on of the fun, to have an apparent progression according to the hour circle XVIII, XIX, XX, &c or to increase in right ascension; while Arcturus, Regulus, the two stars and E Geminorum, Pollux, Procyon, Sirius, and v mmorum, should apparently go back in the order XV, XIV, &c. of the hour circle, fo as to decrease right afcention. But according to De la Land table, excepting & Cygni and Arietis, all thefe 3 P

from the

foregoing Appearan-

pelusionations really take place. With regard to the change from the of declination, every flar in the table should go towards pregoing the fouth; and here we find but three exceptions, in # and a Cygni and p Pifcium. So that, upon the whole, we have but five deviations out of 27 known motions which this hypothesis will not account for; and these exceptions must be resolved into the real proper motion of the stars.

340 If the vepuity of he ftars.

Some circumstances in the quantity of these motions also deserve our notice. In the first place, Arcturus and Sirius being the largest of the stars, and therefore probably the nearest, ought to have the greatest apparent motion both in right ascension and declination; which is agreeable to observation, as appears from the table. 2. With regard to the right ascension only, Arcturus being better fituated to flow its motion, ought to have it much greater; as we find it actually has. Aldebaran, both badly fituated and confiderably fmaller, ought, according to the same rule, to show but little motion, &c.; all of which is confermable to the table. A very firlking agreement with the hyperthesis may also be observed in Castor and Pollux, both of which are pretty well fituated : and accordingly we find that Pollux, for the fize of the flar, shows as much motion in right afcension as we could expect; though it is remarkable that Castor, though equally well placcd. shows no more than half the motion by the table. This is seemingly contrary to the hypothesis: but it must be remembered, that Castor is a double star, and the two of which it confifts are nearly equal to each other in lustre; so that, as we can allow only half the light to each, there is a strong presumption of their being at twice the distance of Pollux, which agrees very well with observation. It might also be observed, that we should be involved in great difficulty by supposing the motion of Castor really to be in the star: for how extraordinary must be the concurrence, that two flars, viz. those that make up this apparently fingle one, should both have a proper motion so exactly alike, that in all our observations hitherto, we have not found them difagree a fingle second either in right ascension, or in in declination, for 50 years together?

241 Arguments rom the

In a postscript to this paper on the motion of the folar system, Mr Herschel brings several additional confirmations of his hypothesis from the works of Mr ions of Mr Mayer. These contain a catalogue of the places of 80 flare observed by Mr Mayer in 1756, and whose places Herschel's he compared with those of the same stars given by Roeappothesis, mer in 1706. From the goodness of the instrument with which Mr Roemer made his observations, Mr Mayer gives it as his opinion, that where the disagreement in the place of a star is but a small, it may be attributed to the imperfection of the inftrument, but that when it amounts to 10" or 15", it is a very probable indication of motion in such a star; and he adds, that when the difagreement is fo much as in some stars which he names (among which is Fomaband, where the difference is 21" in 50 years), he has not the least doubt of a proper motion. The following tables are extractfrom Mr Mayer's work; one contains the flars whose motion agrees with Mr Herschel's hypothesis; expether those that disagree with it, and whose phemakion of the stars themselves, or to some other more bidden caufe.

" From the first table, (says Mr Herschel), we gather that the principal stars, Lucida Lyrz, Capella, " Orionis, Rigel, Fomahand, " Serpentarii, " Aquarii, Arietis, . Perfei, . Andromede, . Tauri, . Ceti, and 20 more of the most distinguished of the second and third rank of the stars, agree with our proposed solar motion; when, on the contrary, the second table contains but a few stars, and not a fingle one of the first magnitude among them, to oppose it. It is also remarkable, that many stars of the first table agree both in right ascention and declination with the supposition of a folar motion; whereas there is not one among those of the second table which opposes it in both directions. This feems to indicate, that the folar motion, is some

¿ Pegañ

Conclusions of them at least, has counteracted, and thereby destroyfrom the ed, the effect of their own proper motion in one direc-Appearaninprobable, that eight flars out of twelve, conappear improbable, that eight stars out of twelve, con-- tained in the latter table, should only have a motion at rechangles, or in opposition to any one given direction. The same may also be said of 19 stars of the former table, that only agree with the folar motion one way, and are as to fense at rest in the other direction; but these singularities will not be near so remarkable when we have the motion of the fun to compound with their

own proper motions.

To delineate the apparent motions of the Stars. Spherical

conchoid

deferibed.

The motions of a Lyra and a Urfa Majoris towards the north, are placed in the first table: to understand the reason of which, it will be necessary to point out the general law by which the apparent declinations of the stars at present under consideration are governed. Let an arch of 90° be applied to a sphere representing the fixed stars, so as always to pass through the apex of the folar motion: then, while one end of it is drawn along the equator, the other will describe on the spherical furface a curve which will pale through the pole of the equator, and return into itself at the apex. This curve, not taken notice of by other authors, Mr Herschel calls a spherical renchoid, from the manner in which it is generated. The law then is, that all the ftars in the northern hemisphere, fituated within the first in the northern hemisphere, situated within the nodated part of the conchoid, will seem to go to the north by the motion of the solar system towards its appear, the rest will appear to go southwards. A similar carries a to be delicated in the southern hemisphere. My five these shares a method of sinding whether any lay makes placed the species is known, will fall without a within the southbold; after which he accounts to the west of ignificate motion in a Lyra and Crambia in fight electrons, and of Rigel both in right ascendes and declication, in the following manner:

"These than use so by species, that we may reasonably suppose them to be appear those that are nearest to Suppose them to be smong those that are nearest to us: and if they had any confiderable motion, it would most likely have been discovered, since the variations of Sirius, Arcturus, Procyon, Castor, and Pollux, &c. have not escaped our notice. Now, from the same principle of the motion of the folar lystem, by which we have accounted for the apparent motion of the latter stars, we may account for the apparent rest of the former. Those two bright stars, a Lyræ and a Orionis, are placed so near the direction of the affigned solar motion, that from the application of the second theorem (No 236), their motion ought to be insensible in right ascention, and not very considerable in declination; all which is confirmed by observations. With respect to Rigel and a Serpentarii, admitting them both as stars large enough to have shown a proper motion, were their fituation otherwise than it is, we find that they also should be apparently at rest in right ascenfion; and Rigel, having fouthern declination, and being a less considerable star than a Orionis, which shows but 11" motion towards the fouth in 50 years, its apparent motion in declination may on that account be also too small to become visible." Our author concludes with a remarkable passage from Mayer, to the following purpole, viz. " If it be possible that the sun has any proper motion of his own, the flars in that part of the heavens towards which he moves, must appear to open and recede from each other, while on the

other hand, those on the applite fide will feem to con- Conclude tract their distances, and come nearer each other." from the "Now (fays Mr Flerfolul), if we recollect what has foregoing been faid of the motion of the stars, we find that those, towards which I suppose the solar system to move, do really recede from each other: for instance, Arcturus from & Lyræ, & Aquilæ and & Aquarii from & Serpentarii, and s Urfæ Majoris; and, on the contrary, those in the opposite part of the heavens do really come nearer each other, as Sirius to Aldebaran, Procyon to & Arietis, Castor, Pollux, Regulus, &c. to « Cari, « Persei, « Andromedæ, &c. It must be added. however, that we cannot expect immediately to perceive any effects of this motion, excepting in such stars as are nearest to us. But as we have at present no other method of judging of the relative distance of the fixed stars than from their apparent brightness, those that are most likely on that account to be affected by a parallax arifing from the motion of the folar fystem, are the very stars which have been pointed out from Mayer's own table."

With regard to the quantity of motion in the folar Velocity of fystem, or the velocity with which the fun and planets the folar change their places in absolute space, Mr Herschel pro-system. poses only a few distant hints. " From the annual

parallax of the fixed stars (fays he), which from my own observations I find much less than it has hitherto been thought to be, we may certainly admit, that the diameter of the earth's orbit, at the distance of Sirius or Arcturus, would not nearly fubtend an angle of one fecond; but the apparent motion of Arcturus, if owing to a translation of the folar system, amounts to no less than 2".7 a-year, as will appear if we compound the two motions of 1' 11" in right afcention,

and 1' 55" in declination into one fingle motion, and reduce it into an annual quantity. Hence we may, in a general way, estimate that the folar motion can certainly not be less than that which the earth has in her

annual orbit."

SECT. IV. Of the different Systems by which the Celeftial Phenomena have been accounted for.

In treating of the various systems which have been invented in different ages, we do not mean to give an account of the various absurdities that have been broached by individuals on this subject; but shall confine ourselves to those systems which have been of confiderable note, and been generally followed for a number of years. Concerning the opinions of the very first astronomers about the system of nature, we are necessarily as ignorant as we are of those astronomers themselves. Whatever opinions are handed down to us, must be of a vallly later-date than the introduction of aftronomy among mankind. If we may hazard a conjecture, however, we are inclined to think that the first opinions on this subject were much more just than those that were held afterwards for many ages. We are told that Pythagoras maintained the motion of Pythagothe earth, which is now univerfally believed, but at reansystem, that time appears to have been the opinion of only a few detached individuals of Greece. As the Greeks borrowed many things from the Egyptians, and Pythagoras had travelled into Egypt and Phenice, it is probable he might receive an account of this hypothefis from thence : but whether he did fo or not, we have

3 P 2

Of the dif- now no means of knowing, neither is it of any imferent Sy- portance whether he did or not. Certain it is howftems by which the ever, that this opnion did not prevail in his days, nor which the Celeftial for many ages after. In the 2d century after Christ, Phenome- the very name of the Pythagorean hypothesis was supnahave preffed by a fyttem erected by the famous geographer been ac- and aftronomer Claudius Ptolemaus. This fyilen, countedfor which commonly goes by the name of the Ptolemaic, he scems not to have originally invented, but adopted Suppressed as the prevailing one of that age; and perhaps made by the Pto-it somewhat more confishent than it was before. He supposed the earth at rest in the centre of the universe. Round the earth, and the nearest to it of all the heavenly bodies, the moon performed its monthly revolutions. Next to the moon was placed the planet Mercury; then Venus; and above that the Sun, Mars, Jupiter, and Saturn, in their proper orbits; then the iphere of the fixed flars; above thefe, two fpheres of what he called crystalline heavens; above these was the primum mobile, which by turning round once in 24 hours, by fome unaccountable means or other, care and all the reft along with it. The primum mobile was: encompassed by the empyrean heaven, which was of as cubic form, and the feat of angels and bleffed spirits. Belides the motions of all the heavens round the earth once in 24 hours, each planet was supposed to have a particular motion of its own; the moon for instance, once in a month, performed an additional revolution, the fun in a year, &c. See Fig. 150.

248 Ptolemy's fustem infufficient.

It is easy to see that, on this supposition, the confused motions of the planets already described could never be accounted for. Had they circulated uniformly round the earth, their apparent motion ought always to have been equal and uniform, without appearing either flationary or retrograde in any part of their In confequence of this objection, Ptolemy was obliged to invent a great number of circles, interferring with each other, which he called epicycles and eccentrics. These proved a ready and essectual salvo for all the defects of his system: as, whenever a planet was deviating from the course it ought on his plan to have followed, it was then only moving in an epicycle or an eccentric, and would in due time fall into its proper path. As to the natural causes by which the planets were directed to move in these epicycles and recentrics, it is no wonder that he found himfelf much at a lofs, and was obliged to have recourse to divinepower for an explanation, or, in other words, to own that his fythem was unintelligible.

Pythago-

This fythem continued to be in vogue till the beginrean lystemning of the 16th century, when Nicolaus Copernicus, revived by a native of Thorn (a city of Regal Pruffia), and a man Coperaicus of great abilities, began to try whether a more fatisfactory manner of accounting for the apparent motions of the heavenly bodies could not be obtained than was afforded by the Ptolemaic hypothesis. He had recourse to every author upon the subject, to fee whether any had been more confiftent in explaining the irregular motions of the flais than the mathematical schools: but he . received no fatisfaction, till he found first from Cicero, that Nicetas the Syraculan had maintained the motion of the earth; and next from Plutarch, that others of the ancients had been of the fame opinion. From the final hints he could obtain from the ancients, Copernicua indeduced a most complete fyslem, capable of folv-

ing every phenomenon in a fatisfactory manner. From Of the difhim this fystem hath ever afterwards been called the ferent sy-Gopernican, and is represented fig. 152. Here the fun which the is supposed to be in the centre; next him revolves the Celestral planet Mercury; then Venus; next, the Earth, with Phenomethe Moon; beyond thefe Mars, Jupiter, and Saturn; na have and far beyond the orbit of Sature, he supposed the been acfixed flars to be placed, which formed the boundaries counted for. of the visible creation.

Though this hypothesis afforded the only natural and Tychonic fatisfactory folution of the phenomena which fo much fystem. perplexed Ptolemy's fystem, it met with great oppofition at first: which is not to be wondered at, cont dering the age in which he lived. Even the famous aftronomer Tycho Brahe could never affent to the earth's motion, which was the foundation of Copernious's Icheme. He therefore invented another lyftem, where-Tig. 151. by he avoided the ascribing of motion to the earth, and at the same time got clear of the difficulties with which Ptolemy was embarrafied. In this fuffern, the earth was supposed the centre of the orbits of the fun and moon; but the fun was supposed to be the centre of the orbits of the five planets; to that the fun with all the placets were by Tychio Beade supposed to turn round the earth, in order to fave the motion of the earth found its axis once in 24 hours. This lyttem was never much followed, the Superiority of the Copernican feheme being evident at first light.

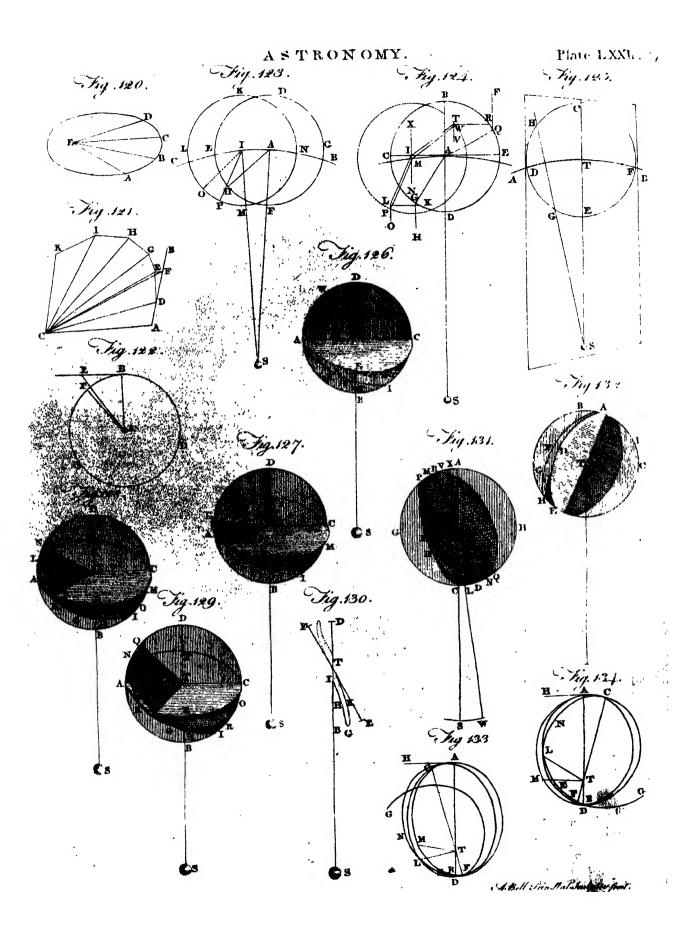

felicine being evident at field light.

The fystem of Coperaires coming from into univer ir quiries ful credit, philosophers began to intuitive into the excles concerning of the planetary motions; and paint, without a triping after earlies upon what has been advanted by a triping at a credit for the planetwe shall content ourselves with gring at a credit fortion, the three famous systems, the Capacitan at a credit fortion and what is sometimes called the Capacitan system.

Des Cartes, the founder of that system which mean cartesian his time has been called the Capacitan, Building about your to have been borrowed from the philosophies. These critics and Epicurus; whe had that every thing was formed by a particular esotion of very minute bodice.

formed by a particular esotion of very minute bodies called atoms, which could not be divided into a fmaller parts. But though the philosophy of Des Cartes re-fembled that of the Corpuscularians, in accounting for all the phenomena of nature, merely from matter and motion: he differed from them in supposing the original parts of matter capable of being broken. this property his Materia Subtilis owes its origin. To each of his atoms, or rather small masses of matter, Des Cartes attributed a motion on its axis, and likewife maintained that there was a general motion of the whole matter of the universe, round like a vortex or whirlpool. From this complicated motion, those particles, which were of an angular form, would have their angles broke off; and the fragments which were broke off, being smaller than the particles from which they were abraded, behoved to form a matter of a more fubtile kind than that made of large particles; and as there was no end of the abrasion, different kinds of matter of all degrees of fineuels would be produced. The finest forts, he thought would naturally separate themselves from the rest, and be accumulated in particular places. The finest of all would therefore be collected in the fun, which was the centre of the universe, whose vortex was the whole ethereal matter in the cre-

ation

Of the dif- ation. As all the planets were immerfed in this vorferent Sy- tex, they behaved to be carried round by it, in differthen by ent times, proportioned to their diffances; those which which the Celestial were nearest the fun circulating the most quickly; and Phenomena those farthest off more slowly; as those parts of a vorhave been tex which are faithest removed from the centre are obaccounted ferved to circulate more flowly than those which are nearest. Besides this general vortex of the sun, each of the planets had a particular vortex of their own by which their fecondary planets were carried round, and any other body that happened to come within reach of it would likewife be carried away.

It is easy to see, from this short account of Des Cartes's fyllem, that the whole of it was a mere petitio principii; for had he been required to prove the existence of his materia fubtilis, he must undoubtedly have failed in the attempt; and hence, though his hypothefis was for some time followed for want of a better, yet it gave way to that of Newton almost as soon as it was propofed.

253 Sir Ifaac N. wton's fy ftem,

The general view of the folar fystem given by this celebrated philosopher, is not different from what has been laid down in the foregoing sections. The fun is placed in or near the centre ; about whom the fix planets, to which a leventh, the Georgium Sidur, is now added, continuelly move with different degrees of velocity, and at different different. The first and neareft to the fun is Merenty, next Vonus, then the Earth and Moon; beyond there is Mars; after him, Jupiter; then the property and last offered, at least as far as discoveries have intrinsect resolved, the Georgian Sidus. Four of thest present planets in they are called, are attended by strong of laterines, as well as the earth. These are, Venue last the Georgian Sidus: of strong last are the fecond, four, the third, five a new the Surrent two, though probably there may be more yet and the week as the fermion yet and the first two, though probably there has a different probably there are different probably the pro nels or diffance.

254 Orbits of elliptical, Ac.

Though these planets uniformly and at all times the planets respect the sun as the centre of their motion, yet they do not always preferve the same distance from him; neither do they all move in the fame plane, though every one of them revolves in an orbit whose plane if extended would pass through the sun's centre. The line in which the planes of any of the planetary orbits crofs the orbit of the earth is called the line of its nodes, and the points of interfection are the nodes themselves. Each of them moves in an orbit somewhat elliptical; and thus fometimes approaches nearer, and at others recedes farther from, the fun than before. This deviation from a circle is called the eccentricity of the orbit; the point where it is farthest distant from the fun is called its aphelion; and where nearest, the perihelion. The eccentricities of the different planets, eccutrici- however, are very different. In Saturn the proportion ies, aphe- of the greatest distance to the least is something less than 9 to 8, but much nearer to this than 10 to 9; at planets in Jupiter; it is fomething greater than that of 11 to 10; in Mars, it exceeds the proportion of 6 to 5; in the earth, it is only in the proportion of about 30 to 29; in Venus still less, being only as 70 to 69; but in Mercury it is much greater than in any of the rest, being little less than that of 3 to 2. The aphehis of all the planets are not fituated on the fame fide of the fun, but in the politions flown fig. 106.; though Of Centific these positions are also variable, as shall be afterwards more fully explained. The eccentricity of the Georgium Sidus is not yet determined, though it is supposed to be less than that of the rest. All of them revolve from west to east; and the most remote is the longest of finishing its course round the fun.

Powers.

256

Each of the planets moves in its orbit round the fun They dein fuch a manner, that the line drawn from the fun to feribe equal the planet, by accompanying the planet in its motion, spaces in ewill describe about the sun equal spaces in equal times, qual times round the There is also a certain relation between the greater aver fin. of these ellipses and the times in which the planets perform their revolutions through them, which may be expressed in the following manner: Let the period or one planet be expressed by the letter A, the greater axis of its orbit by D; let the period of another planet be denoted by B, and the greater B E axis of this planet's orbit by E. Then if C $C - \Gamma$ be taken to bear the same proportion to B as B bears to A; likewise if F be taken to bear the same proportion to E as E bears to D, and G take. to bear the same proportion likewife to F as E bear. to D; then A shall bear the fame proportion to C as D bears to G.

§ 1. Of Centripetal Powers in general.

Before we attempt to give any particular caplanation on this ac's of the causes producing the planetary motions, it will doctrine of be necessary to premise something of Sir Isaac Newton's competal doctrine of centripetal forces, as upon that depends his powers. doctrine of gravitation, and of the whole celefial fystem. The first effect of these powers is, to cause any body projected in a straight line deviate from it, and defende an incurvated one, which shall always be bent towards the centre to which the body is supposed to have a tendency. It is not, however, necessary that the moving body should approach the centre; it may even recede farther from it, notwithstanding its being drawn by it; but this property uniformly belongs to it, that the line in which it moves will be continually concave towards the centre to which the power is directed.

Let A (fig. 107.) be the centre of a force. Let a body in B be moving in the direction of the straight line BC, in which fine it would continue to move if undiffurbed; but being attracted by the centripetal force towards A, the body mult necessarily depart from this line BC; and being drawn into the curve line BD, must pass between the lines AB and BC. It is evident, therefore, that the body is B being gradually turned off from the straight line BC, it will at first be convex towards that line, and concave towards A. And that the curve will always continue to have this concavity towards A, may thus appear: In the line BC. near to B, take any point, as E, from which the line EFG may be so drawn as to touch the curve line BD in some point, as F. Now, when the body is come to F, if the centractal power were immediately to be fuspended, the body would no longer continue to move in a curve line, but, being left to itfelf, would forthwith reaffume a ftraight courfe, and that ftraight courfe would be in the line FG; for that line is in the direction of the body's motion of the point F. But the centripetal force continuing it's energy, the body will be gradually drawn from this line FG fo as to keep in

255

petal Powers.

Centri- the line FD, and make that line, near the point F, to be concave towards the point A; and in this manner the body may be followed in its course throughout the line BD, and every part of that line be shown to be concave towards the point A.

Again, The point A (fig. 108.) being the centre of a centripetal force, let a body at B fet out in the direction of the straight line BC, perpendicular to the line AB. It will be easily conceived, that there is no other point in the line BC to near to A as the point B; that AB is the shortest of all the lines which can be drawn from A to any part of the line BC; all others as AD or AE, being longer than AB. Hence it follows, that the body fetting out from it, if it moved in the line BC, would recede more and more from the point A. Now, as the operation of a centripetal force is to draw a body towards the centre of that force, if fuch a force act upon a refling body, it must necesfarily put that body fo into motion as to cause it move towards the centre of the force: if the body were of itself moving towards that centre, it would accelerate that motion, and cause it to move faster down : but if the body were in such a motion that it would of itself recede from the centre, it is not necessary that the action of a centripetal power should make it immediately approach the centre from which it would otherwise: have receded; the centripetal force is not without effeet if it cause the body to recede more slowly from that centre than otherwise it would have done. the smallest centripetal power, if it act on the body, will force it out of the line BC, and cause it to pass in a bent line between BC and the point A, as has been already explained. When the body, for inflance, has advanced to the line AD, the effect of the centripetal force discovers itself by having removed the body out of the line BC, and brought it to cross the line AD somewhere between A and D, suppose at F. Now, AD being longer than AB, AF may also be longer than AB. The centripetal power may indeed be so strong, that AF shall be shorter than AB; or it may be so evenly balanced with the progressive motion of the body that AF and AB shall be just equal; in the which case the body would describe a circle about the centre A; this centre of the force being also the centre

If now the body, instead of setting out in the line BC perpendicular to AB, had fet out in another line BG more inclined towards the line AB, moving in the curve line BH; then, as the body, if it were to continue its motion in the line BG, would for some time approach the centre A, the centripetal force would cause it to make greater advances towards that centre: But if the body were to fet out in the line BI, reclined the other way from the perpendicular BC, and were to be drawn by the centripetal force into the curve line BK , the body, notwithstanding any centripetal force, would for some time recede from the centre; fince some part at least of the curve line BK hes between the line BI and the perpendicular BC.

Let us next suppose a centripetal power directed toward the point A (Fig. 109.), to act on a hody in B, which is moving in the direction of the ftraight line

the line BC reclining off from AB. If from A reaight lines AD, AE, AF, are drawn to the line prolonged beyond B to G, it appears that AD is

inclined to the line GC more obliquely than AB, Of Centri-AE more obliquely than AD, and AF than AE; petal or, to speak more correctly, the angle under ADG is less than that under ABG, that under AEG is less than ADG, and AFG less than AEG. Now suppose the body to move in the curve line BHIK, it is likewise evident that the line BHIK being concave towards A and convex towards BC, it is more and more turned off from that line; fo that in the point H, the line AK will be more obliquely inclined to the curve line BHIK than the same line AHD is inclined to BC at the point D; at the point I the inclination of the line AI to the curve line will be more different from the inclination of the fame line AIE to the line BC at the point IE; and in the points K and F the difference of inclination will be still greater; and in both, the inclination at the curve will be less oblique than at the straight line BC. But the straight line AB is less obliquely inclined to BG that AD is inclined towards DG; therefore, although the line AH be less obliquely juclined towards the curve HB than the same line AHD is inclined towards DG, yet it is puffible, that the inclination at H may be more obliquely than the inclination at B. The inclination at H may indeed be less oblique than the other, or they may be both the fame. This depends upon the degree of firength wherewith the centripetal force exerts itself during the pallage of the body from B to H: and in like manner the inclinations at I and K depend entirely on the dogstal of firength the court depend entirely on the deposit of frength subsectifit the centripetal force acts in the body left that from H to K: if the centripetal free the subsection of the lines AH and AI deposition of the the body at it and at I, fail to more a stronger in clined to the quest than the large of the more action of the centripetal success of the frength as to reader all task submitted to the inclination of the frength as to reader all task submitted to the inclination of the french at B and St Task Section 1 the large of the submitted to the more actions after a certain market without the subsection of the subsection and the large from the centric fact a single line, that all the lines drawn from the centric to the body shall be equally indrawn from the centre to the body shall be equally incliped to that curve line.

We must farther remark, that if the centripetal Revolution power, while the body increases its distance from the of a body centre, retain sufficient strength to make the lines round a drawn from the centre to the body to become at plained. length less oblique to the curve; then, if this diminution of the obliquity continue, till at last the line drawn from the centre to the body shall cease to be obliquely inclined to the curve, and become perpendicular thereto; from this inftant the body shall no longer recede from the centre, but in its following motion shall again descend, and describe a curve in all respects like that which it has described already, provided the centripetal power, everywhere at the same distance from the body, acts with the same strength. This return of the body may be proved by the following proposition: That if the body in any place, suppofe at I, were to be stopped, and thrown directly backward with the velocity wherewith it was moving forward in that point I, then the body, by the action of the centripetal force upon it, would move back again over the path IHB, in which it had before ad-

Of Centri- vanced forward, and would arrive again at the point B in the same space of time as was taken up in its passage from B to I; the velocity of the body at its return from the point B being the same as that wherewith it

first set out from that point. The truth of this proposition may be illustrated in the following manner: Suppose, in fig. 110. that a body were carried after the following manner through the bent figure ABCDEF, composed of the straight lines AB, BC, CD, DE, EF: let the body then first be supposed to receive an impulse to some point within the concavity of the figure, as G. Now, as this body, when once moving in the ftraight line AB, will continue to move on in this line as long as it shall be left to itself; but being disturbed at the point B by the impulse given it, it will be turned out of this line AB into fome other ftraight line, wherein it will afterwards: continue to move as long as it shall be left to irlelf's therefore, let this impulle have firength fufficient to turn the body into the line BC; then let the body move on undillurbed from B to C: but at C let it read ceive another impulle pointed also towards G, and of sufficient firength to save the body into the line CD; at D let a third impullation in into the line DE; and at E let another tari it sage EE. New, if she body, while morning as as he has be he hopped and turned back as in the last which it was nown forward in the last Ekwith the fame are specified at D, at the impulse at D, at the impulse at D, at the impulse at D, at the body will be LA, with the velocity of last.

Let DE and FE be considered to least the length La, with the velocity last last length La, and let HL be fo drawn as to be equidiffent from the line GE; then, from the second ceive another impulse printed also towards G, and of ..

equidificant from the line GR ; then, from the fecond law of metion, it follows, that after the impulse on the body on E, it will move through the space EI in the same time it would have employed in moving from E to H with the velocity it had in the line DE. In FE prolonged, take EK equal to EI, and draw KL equidificant from GE. Then, because the body is thrown back in the line FE with the fame velocity with which it went forward in that line, if, when the body was turned to E, it were permitted to go straight on, it would pass through EK in the same time as it took up in passing through EI, when it went forward in the line EF. But if, at the body's return to the point E, such an impulse directed toward the point D were to be given it as was sufficient to turn it into the line DE, it is plain that this impulse must be equal to that which originally turned the body out of the line DE into EF; and that the velocity with which the body will return into the line ED is the fame as that wherewith it moved before through this line from D to E. Because EK is equal to EI, and KL and HI being each equidifiant from GE, are by consequence equidistant from each other; it follows, that the two triangular figures IEH and KEL are altogether like and equal to each other. EK there-

fore being equal to EI, and EL equal to KH, and Of Centri-KL equal to HL, it is plain, that the body, after its Powers. return to E, being turned out of the line FE into ED by an impulse acting upon it in E after the manner above mentioned, it will receive fuch a velocity by this impulse as will carry it through EL in the same time it would have taken to go through EK, if it had passed through it undisturbed. It has already been observed, that the time in which the body would pass. over EK, with the velocity wherewith it returns, is equal to the time it took up in going forward from E to I; that is, to the time in which it would have gone through EH with the velocity wherewith it moved from D to E: therefore the time in which the body will puls from E to L, after its return into the line ED, is the same as would have been taken up by the body in passing through the line EH with the velocity wherewith it first moved in the line DE. Since, therefore, EL and EH are equal, the body returns into the line DE with the velocity which it had before in that line .- Again, We may affirm, that the second impulse in E is equal to the first : for as the impulse in E, whereby the body was turned out of the line DE into the line EF, is of such strength, that if the body had been at rest when this impulse had acted upon it, it would have communicated as much motion to it as would have been sufficient to carry it through a length equal to HI, in the time wherein the body would have passed from E to H, or in the time wherein it passed from E to I. In the same manner, on the return of the body, the impulse in E, whereby it is turned out of the line FE into ED, is of fuch strength, that if it had acted on the body at rest, it would have caused it move through a length equal to KL in the same time as the body would employ in passing through EK with the velocity wherewith it returns in the line FE; therefore the fecond impulse, had it acted on the body at rest, would have caused it to move through a length equal to KL in the fame fpace of time as would have been taken up by the body in passing through a length equal to IHI were the first impulse to act on the body while at rest; that is, the effects of the first and second impulse on the body when at rest would be the same: for KL and HI are equal; consequently the second impulse is equal to the first. Thus, if the body be returned through FE with the velocity wherewith it moved forward, it has been shown how, by the repetition of the impulse which acted on it in E, the body will return again into the line DE with the velocity which it had before in that line. By the same method of reasoning it may be proved, that when the body is returned back to D, the impulse which before acted on that point will throw the body into the line DC with the velocity which it first had in that line; and the other impulses being fuccessively repeated, the body will at length be brought back again into the line BA with the velocity wherewith it set out in that line .- Thus these impulfes, by acting over again in an inverted order all their operations on the body, bring it back again through the path in which it had proceeded forward; and this . obtains equally whatever be the number of straight lines whereof this curve figure is composed. Now, by a method of reasoning of which Sir Isaac Newton made much use, and which he introduced into geo. . metry,

Of Centri-metry, thereby greatly enviching that science, we petal might make a transition from this figure, composed of

Powers. a number of straight lines, to a figure of one continued curvature, and from a number of separate impulses repeated at diffined intervals to a continued centripetal force, and show, that because what has been here advanced holds univerfally true whatever be the number of flraight lines whereof the curve figure ACF is composed, and however frequently the impulses at the angles of this figure are repeated; therefore the fame will flill remain true although this figure should be converted into one of a continued curvature; and thefe diffinct impulses should be changed into a continual centripetal force.

> This being allowed, suppose the body in K to have the line AK no longer obliquely inclined to its motion. In this case, if the body be turned back in the manner we have been confidering, it must be directed back perpendicularly to AK; but if it had proceeded forward, it would likewise have moved in a direction perpendicular to AK: confequently, whether it more from this point K backward or forward, it must describe the same kind of course. Therefore, since by being turned back it will go over again the line KIHB, if it be permitted to go forward, the line KL, which it fliall deferibe, will be altogether fimilar to the line

> In like manner we may determine the nature of the motion, if the line wherein the body fets out be inclined, as in fig. 111. down toward the line BA drawn between the body and the centre. If the centripetal power to much increases in thrength as the body approaches, that it can bend the path in which the body moves to that degree as to cause all the lines, AH, AI, AK, to remain no less oblique to the motion of the body than AB is oblique to BC, the body shall continually more and more approach the centre: But if the centripetal power increases in so much less a degree as to permit the line drawn from the centre to the hody, as it accompanies the body in its motion, at length to become more and more creek to the curve wherein the body moves, and in the end, suppose at K. to become perpendicular to it; from that time the body shall rife again. This is evident from what has been faid above; because, for the very same reason, here also the body will proceed from the point K to describe a line altogether fimilar to that in which it has moved from B to K. Thus it happens as in the pendulum, which, all the time it approaches a perpendicular position towards the horizon, descends more and more; but as fron as it is come into that fituation, it immediately rites again by the same degrees as it descended before: fo here the body more and more approaches the centre all the time it is moving from B to K; but thenceforward it rifes from the centre again by the fame degree as it approached before.

> If, as in fig. 112. the line BC be perpendicular to AB; then, as has already been observed, the centripetal power may be fo balanced with the progressive motion of the body, that it may keep moving round the centre A constantly at the same distance; as the hody does when whiled about any point to which it is tied by a firing. If the centripetal power be too weak to produce this effect, the motion of the body will prefently become oblique to the line drawn from

itself to the centre; but if it be stronger, the body-Of Centrimust constantly keep moving in a curve to which a line potal drawn from it to the body is perpendicular.

If the centripetal power change with the change of distance, in such a manner that the body, after its motion has become oblique to the line drawn from itfelf to the centre, shall again become perpendicular thereto; then the body shall, in its subsequent motion, return again to the diffance of AB, and from that distance take a course similar to the former; and thus, if the body move in a space void of all resistance, which has been all along supposed, it will continue in a perpetual motion about the centre, descending and ascending from it alternately. If the body, fetting out from B (fig. 113.) in the line BC perpendicular to AB, describe the line BDE, which in D shall be oblique to the line AD, but in E shall again become erect to AE drawn from the body at E to the centre A; then from this point E the body shall describe the line EFG estirely fimilar to BDE, and at G shall be at the same distance as it was at B: and the line AG thall be creek to the body's motion. Therefore the body shall proceed to describe from G the line GHI sitogether fundar to the line GFE, and at I it will have the lame distance from the centre as it had at E; and also have the line AI erect to its motion : so that its subsequent motion must be in the line IKL similar to IKG, and the distance AL count to AG. Thus the body will go on in a perpetual sound without confing, alternately enlarging and countries in the same area. the centre.

the centre.

If it to happen that the point E all and the line BA, continued beyond A t then the point in the BA, continued beyond A t then the point in the point in this case describe a simple work line, some the centre A, like the line BAE in the centre A, like the line BAE in the line at the prolonged beyond A, the fount I can the line at prolonged beyond A, and the tourt I can B; to that the longed beyond A, and the point L on B; so that the hody will deferibe a line like the curve line BEGI in fig. 145, in which the opposite points B and G are equally distant from A; and the opposite points E and L are also equally distant from the same point A. In other cases the body will have a course of a more complicated nature.

Thus it must be apparent how a body, while it is constantily attracted towards the centre, may notwithstanding by its progressive motion keep itself from falling down to the centre, describing about it an endless circuit, sometimes approaching and sometimes icceding from it. Hitherto, however, we have supposed, that the centripetal power is everywhere of equal fireigth at the fame diffance from the centre: and this is indeed the cafe with that power which keeps the planets in their orbits; but a body may be kept on in a perpetual circuit round a centre, although the centripetal power he kept moving in any curve line whatever, that shall have its concavity turned everywhere towards the centre of the force. To illustrate this, we shall in the first place propose the case of a body moving the incurvated figure ABCDE (fig. 116.), which is composed of the straight lines, AB, BC, CD, DE,

Of Centri- and EA; the motion being carried on in the following petal manner: Let the body first move in the line AB with Powers any uniform velocity. When it is arrived at the point B, let it receive an impulse directed towards any point F taken within the figure; and let the impulse be of fuch a strength as to turn the body out of the line AB into the line BC: The body after this impulse, while left to itself, will continue moving in the line BC. At C let the body receive another impulse directed towards the same point F, of such a strength as to turn it from the line BC into CD. At D, let the body, by another impulse, directed likewise to the point F, be turned out of the line CD into DE. At E, let another impulle, directed likewise towards to point F, turn the body from the line DE into EA: and thus the body will, by means of these impulses, be carried through the

whole figure ABCDE.

whole figure ABCDE.

Again, When the body is come to the point A, if it there received another impulse directed like the refl is the point F, and of luch a degree of directed like the refl is turn it into the line AB, wherein it first amoved; the body will then return into this line with the take wiperity it had ariginally. To underlying this, let AB be prolonged beyond B at pleasure, impulse to an another than the first AB drawn stepping and the first AB drawn stepping and the line and the first CHI be drawn stepping and the line and the first and remains any manufactured and the line and the first and the line and l in the insurer, if CI be a way garallel to CF, C with the vertice is lime time it is not contained in I with the lime attra up is moving an attra up is moving a way way with it moved the lime of the color will. It has been excellent as according to the color will, for the innecessarian as according to move theoligh. DM with the welectity which is hearth the line DE, in the lapse time it would employ in moving through BO with its original velocity. Lafly, if EN he takes equal to DM, and NO he drawn parallel to EF a likewise, if AP to taken equal to EO, and PQ be drawn wife, if AP to taken equal to EO, and PQ be drawn parallel to AF; then the body, with the velocity wherewith it returns into the line AB, will pals through AQ in the time it would have employed in passing through BG with its original velocity. Now as all this follows directly from what has been delivered concerning oblique impulies imprelled upon bodies in motion; so we malt here observe farther, that it can be proved by geometry, that AQ will always be equal to BG; which being granted, it follows, that the body has returned into the line AB with the fame velocity which it had when it first moved in the line; for the velocity with which it returns into the line AB, will carry it over the line AO in the fame time as would have been taken up in its palling over an equal line BC with the original velocity.

The conclusion naturally deduced from the above reasoning is, that by means of a centripetal and projectile force, a body may be carried round any fixed

Vol. II. Part II.

point in a curve figure which shall be concave towards Of Co it, as that marked ABC, fig. 117. and when it is returned to that point from whence it fet out, it shall recover again the velocity with which it departed from that point. It is not indeed always necessary that it A body should return again into its first course, for the curve may be line may have some such figure as ABCDBE in moved in fig. 118. In this curve line, if the body set out from any curvi-B in the direction BF, and moved through the line lineardirection by BCD till it returned to B; here the body would not mears of enter again into the line BCD, because the two parts centripetal* BD and BC of the curve line make an angle at the force. point B: so that the centripetal power, which at the point B would turn the body from the line BF into the curve, will not be able to turn it into the line BC from the direction in which it returns to the point B. A forcible impulse must be given the body in the point B to produce that effect. If, at the point B, whence the body fets out, the curve line return into itself, as in fig. 117. then the body, upon its arrival again at B, may return into its former course, and thus make an enfiles circuit about the centre.

The force requisite to carry a body in any curve line Calculation

interraption,

proposed, is to be deduced from the curvature which of the force the figure has in any part of it. Sir Isaac Newton has requisite to laid down the following proposition as a foundation for dv in any discovering this, viz. that if a line be drawn from some curve line. fixed point to the body, and remaining by one extreme united to that point, it be carried round along with the body; then if the power whereby the body is kept in its course, be always pointed to this fixed point as a centre, this line will move over equal spaces in equal portions of time. Suppose a body were moving through the curve line ABCD (fig. 120.), and passed over the arches AB, BC, CD, in equal portions of time; then if a point, as E, can be found from whence the line EA being drawn to the body in accompanying it in its motion, i thall make the spaces EAB, EBC, and ECD, over which it passes, equal where the times are equal; then is the body kept in this line by a power always pointed to E as a centre. To prove this, suppose a body set out from the point A, fig. 121. to move in the straight line AB; and after it had moved for fotue time in that line, it were to receive an impulse directed to some point, as C. Let it receive that impulse at D, and thereby be turned into the line DE; and let the body, after this impulse, take the same time in passing from D to E that is employed in passing from A to D. Then the straight lines CA, CD, and CE being drawn, the triangular spaces CAD and CDE are proved to be equal in the following manner: Let EF be drawn parallel to CD. Then, it follows, from the second law of motion, that fince the body was moving in the line AB when ceived the impulse in the direction DC, it will have moved after that impulse through the line DE in the same time as it would have moved through DF, provided it had received no diffurbance in D. But the time of the body's moving from D to E is supposed to be equal to the time of its moving through AD; therefore the time which the body would have employed in maine through DF, had it not been disturbed in D, is to the time wherein it moved through AD: confequently DF is equal in length to AD; for if the body had gone on to move through the line AB without

3 Q

Powers.

matter in

of Centri- interruption, it would have moved through all the parts of it with the same velocity, and have passed over equal parts of that line in equal portions of time. Now CF heing drawn, fince AD and DF are equal, the triangular space CDF is equal to the triangular space CAD. Farther, The line EF being parallel to CD, it follows from the 37th proposition of Euclid's first book, that the triangle CED is equal to the triangle CFD: therefore the triangle CED is equal to the triangle CAD.

In like manner, if the body receive at E another impulse directed toward the point C, and be turned by that impulse into the line EG; if it move afterwards from E to G, in the same space of time as was taken up by its motion from D to E, or from A to D; then CG being drawn, the triangle CEG is equal to CDE. A third impulse at G, directed as the two former to C, whereby the body shall be turned into the line GH, will have also the like effect with the rest. If the body move over GH in the same time as it took up in moving over EG, the triangle CGH will be equal to the triangle CEG. Laftly, If the body at H be turned by a fresh impulse directed towards C into the line HI, and at I by another impulse directed also to C be turned into the line IK; and if the body move over each of the lines HI and IK in the same time as it employed in moving over each of the preceding lines AD, DE, EG, and GH: then each of the triangles CHI and CIK will be equal to each of the preceding. Likewise, as the time in which the body moves over ADE is equal to the time of its moving over EGH, and to the time of its moving over HIK; the space CADE will be equal to the space CEGH and to the space CHIK. In the same manner, as the time in which the body moved over ADEG is equal to the time of its moving over GHIK, so the space CADEG will be equal to the space CGHIK. From this principle Sir Isaac Newton demonstrates the above-mentioned proposition, by making the transition from this incurvated figure compoled of straight lines, to a figure of continued curvation; and by showing, that since equal spaces are de-Scribed in equal times, in this present figure composed of straight lines, the same relation between the spaces. described, and the times of their description will also. have place in a figure of one continued curvature. He fordeduces from this proposition the reverse of it; proves, that whenever equal spaces are continualforce directed to the centre at which the spaces ter-

Having thus endeavoured to illustrate the fundamental principle of the Newtonian philosophy, at least as further it regards the motion of the planets and heaven-1 dedies, we shall now proceed to the more particular application of it. The first thing undertaken by Sir Isac in order to explain those motions, is to demonfirate, that in the celefial spaces there is no fen-No femble fible matter. That the heavenly bodies fuffer no fenfible refistance from any matter of this kind, is evident the celetial from the agreement betwixt aftronomical observations ages with regard to the time in which the planets have ten found to perform their revolutions. Des Cartes were, was of opinion, that the planets might be their courses by means of a fluid matter. their courses by means of a fluid matter,

which continually circulating round, should carry the Of Centelplanets along with it; and there is one appearance which feems to favour this opinion, viz. that the fun turns round his axis the fame way the planets move; the earth also turns round its axis the same way as the moon turns round the earth; and the planet Tupiter turns round his axis the fame way that his fatellites revolve round him. It might therefore be supposed, that if the whole planetary region were filled with a fluid matter, the fun, by turning round on his own axis, might communicate motion first to that part of the fluid which was contiguous, and by degrees propagate the like motion to the parts more remote. After the same manner the earth might communicate motion to this fluid to a degree fufficient to carry round the moon; and Jupiter might communicate the like to the diffence of its fatellites. This system has been particularly examined by Sir Masc Newton; who finds, that the velocities with which the parts of this fluid thould move in different distances from the centre of motion, will not agree with the motions observed in the different planets; for inflance, that the time of one entire circulation of the fluid wherein Jupiter should fwim, would bear a greater proportion to the time of one entire circulation of the fluid where the carth is, than the period of Jupiter bears to that of the earth. He proves also, that the planet cannot circulate in fuch a duid, so as to keep long in the same course, unless the planet middle contiguous field are of the same dentity, and the planet is a same field are of the same velocity as the name. There is also mitter remark made on this minute by the that same vivilging faculty the continuous at the centre of the made. The first in particular, by communicating stations to the first in particular, by communicating stations to the first while the made in the middle from test to meet the middle from the first middle forms account to the first, unless some account meaning the first of meeting stations of the first would be a made the middle for more than the first would remain the that whole should the property would continue the third were limited this last of more would continue the third were limited. earth is, than the period of Jupiter bears to that of this loss of motion would continue till there would remile no lwater & revolution in the fun than in the outermon part of the fund, to that the whole would turn together about the axis of the fun like one folid globe. We must likewise observe, that as the planets do not move in perfect circles round the fun, there is a great. er diffance beeween their orbits in some places than others. For instance, the distance between the orbitof Mars and Venus is near half as great again in some parts of their course as in others. Now here the fluid in which the earth should fwim, must move with a less. rapid motion where there is this greater interval between the contiguous orbits; but on the contrary, where the space is straitest, the earth moves more flowly than where it is wideft.

Again, If our globe of earth fwam in a fluid of equal dentity with the earth itself, that is, in a fluid more dense than water, all bodies put in motion here upon the earth's furface must suffer a great resistance by it; whereas Sir Isaac Newton has made it evident, by experiments, that bodies, falling perpendicularly through the air, suffer only about a hundred and fixtieth part of the relistance from it that they meet with

in water.

Thefe

Motions of

262 Objections to a plenum.

These experiments are applied by Sir Isaac yet farthe Primather to the general question concerning the absolute ry Planeta. plenitude of space. He objects against the filling of all space with a subtile sluid, after the manner of Des Cartes. That all bodies must be immeasurably resisted by it. And lest it should be thought that this objection might be evaded, by afcribing to this fluid fuch very minute and fmooth parts as might remove all adhesion or friction between them, whereby all refistance would be loft, Sir Isaac proves, that fluids must result from the inactivity of their particles, and that water and the air refift almost entirely on this account; so that in this fubtile fluid, however fmooth and lubricated the particles might be, yet if the whole were as denfe as water, it would refift very near as much as water doest' And whereas such a sluid, whose parts are absolutely close together without any intervening spaces, must be a great deal more dense than water, it must also resist more in proportion to its denfity, unless we suppose the matter of which this fluid is compoled not to be endowed with the same degree of inscrivity with other matter: But if you disprise any futilitance of the property fo univerfally belonging to all other matter, without impropriety of speech is can force be called by this name. Sir Mine Mio mude an experiment to try in particular, whether the internal pants of bodies foffered any residence; and the vefult did indeed appear to fa-

proportion explained.

any resistance; and the result did indeed appear to favour some small degree of resistance; but so very little as to like a doubtest self-than the effect did not arise that the effect did not arise that the effect did not arise that the primary Planets.

The planets of the primary Planets of the primary planets that a line expected that the primary planets manner that a line explanets is until the primary planets that a line explanets is until the primary planets that a line explanets is until these and the south of the primary planets is until these and the south of the primary planets is until these and the south of the primary and look property in the planetary additions property that a they are continually planetary and lone proves that they are continually acked upon by a power directed towns the lunius the centre. It has also been observed, that if the strength of the centripetal power were fuitably accommodated everywhere to the motion of any body round a centre, the body might be carried in any bent line whatever, whose concavity should be everywhere turned towards the centre of that force; and likewife that the firength of the centripetal force in each place was to be collected from the nature of the line wherein the body moved. Now fince each of the planets moves in an ellipfis, having the fun in one of its foci, Sir Isaac Newton demonstrates, that the strength of this power is reciprocally in the duplicate proportion of the distance from the dun. This proportion may be explained in the following manner: Suppose several distances to bear to each other the proportions of the numbers 1, 2, 3, 4, 5; that is, let the fecond distance be double the first, the third three times, the fourth four times, and the fifth five times as great as the first: multiply each of these numbers by itself, and I multiplied by I produces still 1, 2 multiplied by 2 produces 4, 3 by 3 produces 9, 4 by 4 produces 16, and 5 by 5 produces 25; this being done, the fractions \(\frac{1}{4}\), \(\frac{1}{16}\) and \(\frac{1}{4}\), will respect tively express the proportion which the centripetal power in each of the following distances bears to the

power at the first distance; for in the second distance, Motious of which is double the first, the centripetal power will be the Primaone fourth part only of the power at the first distance; ry Planets at the third distance, the power will only be one-ninth part of the first power; at the fourth distance, the power will be only one-fixteenth; and at the fifth distance only one twenty fifth, of the first power. Thus is found the proportion in which the centripetal power decreases, as the distance from the fun increases within the compals of one planet's motion. How it comes to pass that the planet can be carried about the sun by this centripetal power in a continual round, fometimes rifing from the fun, then defcending again as low, appears from what has been already faid concerning cen-

tripetal forces.

In order to know whether this centripetal power Centripetal extends in the same proportion throughout the system, power proand confequently whether all the planets are influenced tend by it. Sir Isaac inquires what relation there ought to throughout be between the periods of the different planets, provided the tyltem. they were acted upon by the same power, decreasing throughout in the proportion above mentioned; and he finds, that the period of each, in this case, would have that very proportion to the greater, axis of its orbit which has been already related: which puts it beyond a doubt, that the different planets are preffed towards the fun in the same proportion to the distances as one planet is in its feveral distances; whence it is justly Centripetal concluded, that there is fuch a power acting towards power dethe fun in the forefaid proportion at all distances from fined. it. This power, when referred to the earth, Sir Ifanc calls gravity; when to the fun, attraction; and to the planets, centripetal force. By these names, however, he defigns only to fignify a power endowed with the properties above mentioned; but by no means would have it understood as if these names referred any way to the cause of it.

46 But now (fays Mr Pemberton) in these demon- Fiew of Sec. strations, some very minute inequalities in the motion Isaac Newof the planets are neglected; which is done with a ton, Philips great deal of indement; for whatever be their cause supply, great deal of judgment; for whatever be their cause, p. 175, the effects are very inconsiderable, they being so exceedingly small, that some astronomers have thought Minute vafit wholly to pass them by. However, the excellen-rictions in cy of this philosophy, when in the hands of fo great a the planegeometer as our author (Sir Isaac Newton), is such, tions acthat it is able to trace the least variations of things up counted to their causes. The only inequalities which have for. been observed common to all the planets are, the motion of the aphelion and the nodes. The transverse axis of each orbit does not remain always fixed, but moves about the fun with a very flow progreffive motion; nor do the planets keep constantly in the same planes, but change them and the lines by which thefe planes interfect each other by infentible degrees. The Motion of first of these inequalities, which is the motion of the the apheaphelion, may be accounted for, by supposing the gra-ted for. vitation of the planets towards the fun to differ a little farther from the forementioned reciprocal duplicate proportion of the distances; but the second, which is the motion of the nodes, cannot be accounted for by any power directed towards the fun; for no fuch power can give it any lateral impulse to divert it from the plane of its motion into any new plane, but of neceffity must be derived from some other centre. Where

Motions of that power is lodged, remains to be discovered. Now the Prima- it is proved, as shall be afterwards explained, that the three primary planets, Saturn, Jupiter, and the Earth, which have fatellites revolving about them, are endowed with a power of caufing bodies, in particular those fatcllites, to gravitate towards them with a force which is reciprocally in the duplicate proportion of their diflances; and the planets are, in all respects in which they come under our confideration, so similar and alike, that there is no reason to question but they have all the same property, though it be sufficient for the present purpose to have it proved of Japiter and Saturn only; for these planets contain much greater quantities of matter than the reft, and proportionally exceed the others in power. But the influence of theletwo planets being allowed, it is evident how the planets come to shift their places continually; for each of the planets moving in a different plane, the action of Jupiter and Saturn upon the rest will be oblique to the planes of their motion, and therefore will gradually draw them into new ones. The same action of thefe two planets upon the rest will likewife cause a progressive motion; and therefore will gradually drawsthem into new ones. The same action of thele two planets upon the rest will likewise cause a progressive motion of the aphelion; so that there will be no necessity for having recourse to the other cause for this motion, which was before hinted at, viz. the gravitation of the planets towards the fun differing from the exact duplicate proportion of their distances. And, in the last place, the action of Jupiter and Saturn upon each other will produce in their motions the fame inequalities as their joint action produces upon the rest. All this is effected in the same manner as the sun produces the same kind of inequalities and many others in the motion of the moon and other fecondary planets; and therefore will be best apprehended by what is faid afterwards. Those other irregularities in the motion of the secondary planets have place likewise here, but are too minute to be observable, because they are produced and rectified alternately, for the most part of the time of a fingle revolution; whereas the motion of the aphelion and nodes which increase continually become fentible after a long faries of years, Yet some of these other inequalities are discernible in Supiter and Jupiter and Saturn; in Saturn chiefly: for when Jupiter, kenes each who moves fafter than Saturn, approaches to a con-Wher's mo-junction with him, his action upon the latter will a little retard the motion of that planet; and by the reciprocal action of Saturn, he will himfelf be accelerated. After conjunction, Jupiter will again accelerate Saturn, and he likewife retarded in the fame degree as before the first was retarded and the other accelerated. Whatever inequalities besides are produced in the motion of Saturn by the action of Jupiter upon that planet will be fufficiently restified by placing the focus of Saturn's ellipsis, which should otherwise be in the fun,

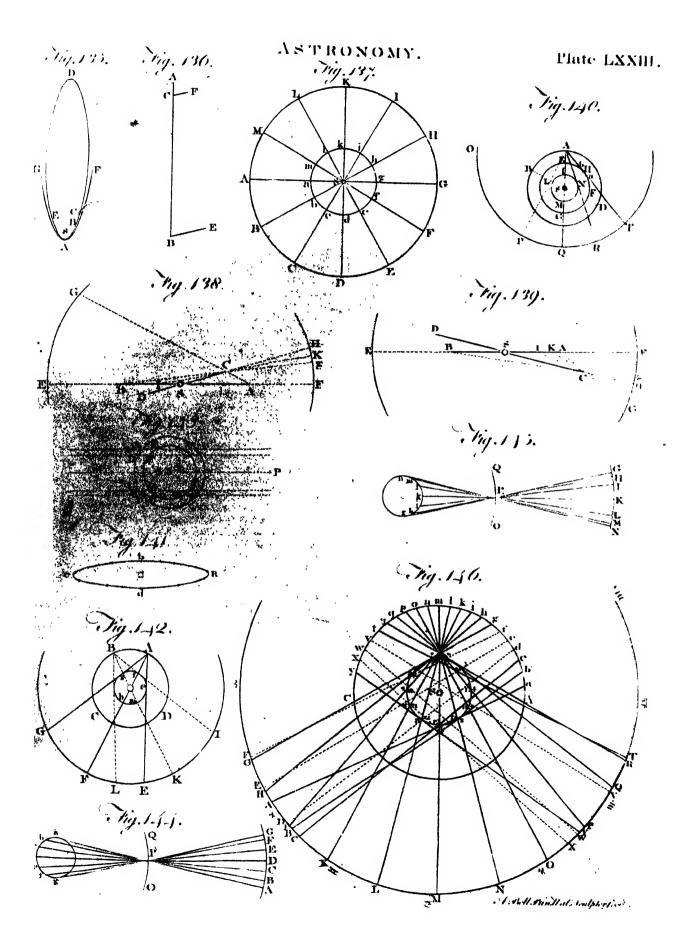

in the common centre of gravity of the fun and Jupi-Motions of And all the inequalities of Jupiter's metions, the Primacaused by the action of Saturn upon him, are much ry Planets. less considerable than the irregularities of Saturn's motion. This one principle therefore of the planets having a power as well as the fun to cause bodies gravitate towards them, which is proved by the motion of the secondary planets to obtain in fact, explains all the irregularities relating to the planetary motions ever obferved by aftronomers (A).

ss Sir Haac Newton after this proceeds to make an Method of improvement in astronomy, by applying this theory to correcting the farther correction of their motions. For as we tary mohave here observed the planets to possess a principle of tions. gravitation as well as the fun; fo it will be explained at large hereafter, that the third law of motion, which maker action and reaction equal is to be applied in this case, and that the fun does not only attract each planet, but in also itself attracted by them; the force wherewith the planer is acted on, bearing to the force wherewith the ins itself is acted upon at the same time, the proportion which the quantity of matter in the fina bears to the quantity of matter in the planet. From the action of the fun and planet being thus mutuals Sir Mante Menton prover thus the inn and planet Sun moves

tual. Sir finite Menton proves thus the ign and planet Sun moves will deferribe dignt their common sentre of gravity fi. round the milar elliples a and then that the transvarie sais of the common centre of elliples, which would be described about the fun at refiguration of in the fame time, the fame injurious as the granter and another of folid matter in the two soil allows the fame at refiguration and the first of two mean productions in the fame and the granter of another in the fame and the granter of another in the fame and the granter of product and another in the planets will be admitted, where the many the fame and the fame of the planets will be family to the product of the many finite control of the product of the fame Newton protes, that if the for sed planet move round thris common centile of gravity, yet to an eye placed in the planet, the spaces which will appear to be described shout the sun will have the fame relation to the times of their description as the real space would if the fus were at rest. I further afferted, that fuppoling the planets to move round the fun at rell, and to be satracted by a power which should everywhere act with degrees of strength reciprocally in the duplicate proportions of their diffunces; then the periods of the planets, must observe the same relations to their distances as astronomers have found them to do. But here it must not be supposed, that the observations of aftronomers absolutely agree without any the least difference; and the prefent correction will not cause adeviation

260 Sacuen in-

> Professor J. Robifon, however, informs us in his paper on the Georgium Sidus (Edinburgh Philosophical infactions. Vol. I.). That all the irregularities in the planetary motions cannot be accounted for from the of gravitation; for which reason he was obliged to suppose the existence of planets beyond the orbit of the even before the discovery of the Georgium Sidus. M. de la Lande also has observed some unaccountable madities in the motion of Saturn for more than 30 years palt.

Motions of deviation from any one aftronomer's observations so the Secon- much as they differ from one another; for in Jupiter, where this correction is greatest, it hardly amounts to the 3000th part of the whole axis.

272 Argument eternity of the world.

"Upon this head, I think it not improper to mention a reflection made by our excellent author upon against the these small inequalities in the planets motions, which contains in it a very strong philosophical argument against the eternity of the world. It is this, that these inequalities must continually increase by flow degrees, till they render at length the present frame of nature unfit for the purposes it now serves. And a more convincing proof cannot be defired against the present constitution's having existed from eternity than this, that a certain period of years will bring it to an end. I am aware, that this thought of our author has been represented even as impious, and as no less than casting a reflection upon the wifdom of the Author of nature for framing a perishable work. But I think so bold an affertion ought to have been made with fingular caution: for if this remark upon the increasing irregularities in the heavenly motions be true in fact, as it really is, the imputation must return upon the affertor, that this does not detract from the divine wildom. Certainly we cannot pretend to know all the omniscicut Creator's purpoles in making this world, and therefore cannot pretend to determine how long he defigned it should last and it is sufficient if it endure the time defigued by the Author. The body of every soinal home the unlimited willow of the Author no lefs, many he many respects more, than the larger frame of manner and yet we have the rane all designed to last have fined frace of time?

1 & The Marine of the lateredary Planets explained from the Principles foul down in § 1.

Whe seculitary of the Armsonian Philosophy is dif-

percepts even more in its folution of the motions of ther secondary than in those of the primary planets; for thus not only all the irregularities formerly discovered by aftronomers in their motions are folved in a fatisfactory manner, but feveral others are differented of fuch a complicated nature that they rould sever bediffinguished into proper heads. Thefe, however, are now not only found out from their causes, which this philusophy has brought to light; but the dependence efithem upon their causes is also shown in such a perfeet manner, that the degree of them may be exactly computed. Thus Sir kinac Newton found means to compute the moon's motion to exactly, that he framed a sheary from which the place of that planet may at all times be computed very nearly, or altogether, as exactly as the places of the primary planets themselves; which is much beyond what the greatest astronomers could

conduties tracked y their Primarics.

The first thing demonstrated of these secondary planets is, that they are drawn towards their respective primaries in the fame manner as the latter are attracted be the fun. That each fecondary planet is kept in its orbit by a power directed towards its primary, &c. is proved from the phenomenon of the satellites of Jupiter and Saturn; because they move in circles, as faras we can observe, about their respective primaries with an equable course, the primary being the centreof each orbit: and by comparing the times in which

the different satellites of the same primary persorm their Motions of periods; they are found to observe the same relation to the Seconthe distances from their primary, as the primary planets dary Plaobserve in respect of their mean distances from the fun. The same thing holds good also with regard to the earth and moon; for the is found to mo : round the earth in an ellipsis after the same manner as the primary planets do about the fun, excepting only fome small irregularities in her motions, the cause of which will be particularly explained in what follows; whereby it will appear that they are no objections against the earth's acting on the moon in the same manner as the fun acts on the primary planets; that is, as Jupiter

and Saturn act upon their fatellites.

piter and Saturn, the power of each of thefe planets Jupiter and may be measured to a very considerable distance; for Saturn disthe diffance of the outermost fatellite in each of these their fatelplanets exceeds feveral times the distance of the inner-lites. moft. The force of the earth upon the moon, however, at different distances, is more confirmed by the following confideration than any analogical reasoning. Gravity re-It will appear, that if the power of the earth by which tains the it retains the moon in her orbit, he supposed to act at moon in all distances between the earth and moon, according her orbit. to the rule already mentioned, this power will be fufficient to produce upon bodies near the furface of the earth all the effects ascribed to the principle of gravity. This is discovered by the following method: Let A (in fig. 122.) represent the earth, B the moon, BCD the moon's orbit; which differs little from a circle of which A is the centre. If the moon in B were left to itself to move with the velocity it has in the point B. it would leave the orbit, and proceed straight forward in the line BE which touches the orbit in B. Suppose the moon would upon this condition move from B to E in the space of one minute of time: By the action of the earth upon the moon, whereby it is re-Her motion tained in its orbit, the moon will really be found at particularly the end of this minute in the point F, from whence a explained. fersight line drawn to A shall make the space BFA in the circle equal to the triangular space BEA; so that the moon in the time wherein it would have moved from B to E, if left to itself, has been impelled to. wards the earth from E to F. And when the time of the moon's passing from B to F is small, as here it is only one minute, the distance between E and F scarce differs from the space through which the moon would descend in the same time if it were to fall directly down from B toward A without any other motion. AB, the diffance of the moon from the earth, is about 60 of the semidiameters of the latter; and the moon completes her revolution round the earth in about 27 days 7 hours and 43 minutes: therefore the space EF will here be found by computation to be about 164 fect. Confequently, if the power by which the moon is retained in its orbit be near the furface of the earth greater than at the distance of the moon in the duplicate proportion of that distance, the number of feet a body would descend near the surface of the earth, by Calculation the action of this power upon it, in one minute, would of the velobe equal to the number 164 multiplied twice into the city of fallnumber, 60; that is, to 58050. But how fast bodies

the pendulum; and by the exacteft experiments, they

By the number of fatellites which move round Ju-Power of

fall near the furface of the earth may be known by

Motions of are found to descend the space of 16th feet in one sethe Secon- cond; and the spaces described by falling bodies bedasy Pla- ing in the duplicate proportion of the times of their fall, the number of feet a body would describe in its fall near the furface of the earth in one minute of time. will be equal to 161 twice multiplied by 60; the same as would be caused by the power which acts upon the

278 Earth and about their commion centre of gravity.

In this computation the earth is supposed to be at moon move rest: but it would have been more exact to have supposed it to move, as well as the moon, about their common centre of gravity; as will eafily be understood from what has been already faid concerning the motion of the fun and primary planets about their common centre of gravity. The action of the sun upon the moon is also here neglected; and Sir Isaac Newton shows, if you take in both these considerations, the present computation will best agree to a somewhat greater distance of the moon and earth, viz. to: 604 lemidiameters of the latter, which distance is more conformable to astronomical observations; and these computations afford an additional proof that the action of the earth observes the same proportion to the distance which is here contended for. In Jupiter and Saturn this power is so far from being confined to a small-extent of space, that it not only reaches to several satellites at very different distances, but also from one planet to another, nay, even through the whole planetary lystem; consequently, there is no appearance of reason why this power should not act at all distances, even at the very furfaces of these planets, as well as faither off. But from hence it follows, that the power which retains the moon in her orbit is the fame us that which causes bodies near the surface of the earth to gravitate; for fince the power by which the earth acts on the moon will cause bodies near the furface of it to descend with all the velocity they are found to do, it is certain no other power can act. upon them besides; because, if it did, they must of necessity descend swifter. Now, from all this, it is at length very evident, that the power in the earth which we call gravity extends up to the moon, and decreases in the duplicate proportion of the increase of the disstance from the earth.

Actions of the fun upon the fecondary planets.

Thus far with respect to the action of the primary. planets upon their fecondaries. The next thing to be shown is, that the fun likewife acts upon them. For this purpose we must observe, that if to the motion of the fatellite whereby it would be carried round its primary at reft, we superadd the same motion, both in regard to the velocity and direction, as the primary itfelf has, it will describe about the primary the same orbit with as great regularity as if the primary hadbeen indeed at rest. This proceeds from the law of motion, which makes a body near the furface of the earth descend perpendicularly, though the earth be in fo (wift a motion, that if the falling body did not partake of it, its descent would be remarkably oblique; and that a body projected describes in the most regular manner the same parabola, whether projected in the direction in which the earth moves, or in the opposite rection, if the projecting force be the same. From is we learn, that if the fatellite moved about its priary with perfect regularity, belides its motion about the primary it would have the same progressive velo-

city with which the primary is carried about the fun, Motions t in a direction parallel to that impulse of its primary: the Secon-And, on the contrary, the want of either of these, in dary Plaparticular of the impulse towards the fun, will occadien great inequalities in the motion of the fecondary planet. The inequalities which would arise from the absence of this impulse towards the sun are so great, that by the regularity which appears in the motion of the secondary planets, it is proved, that the fun communicates to them the same velocity by its action as it gives to their primary at the same distance. For Sir Secondary Isaac Newton informs us, that upon examination he planets found, that if any of the fatellites of Jupiter were at-equally attracted by the fun more or less than Jupiter himself at tracted by the same distance, the orbit of that satellite, instead of with their being concentrical to Jupiter, would have its centre primaries. at a greater or leffer distance than the centre of Juniter from the fun, nearly in the Subduplicate proportion of the difference between the fun's action upon the fatellite and upon Jupiter. Therefore, if any fatellite were attracted by the fun but one hundredth part more or less than Jupiter is at the same distance, the orbit of that fatellite would be distant from the centre of Jupiter no less than a fifth part of the outermost satellite from Jupiter; which is almost the whole distance of the innermost satellite. By the like argument, the fatellises of Saturn gravitate towards the fun as much as Saturn itfelf at the same diffunce, and the moon as 1. 2. 10. 3 much as the earth.

Thus it is proved, that the few acts upon the fewer. Whence dary planets as much as upon the primaries at the families in the difference in the fewer whence difference is the fewer with the first in the of the fun upon bodies is requestrally in the distributions of the fun upon bodies is requestrally in the distributions of proportion of the difference; the fewer the fecondary ary planet planets being fometimes make the function to the arise, primary, and fometimes more stabilities that we have acted upon in the fewer with the machine and the fewer with the fewer wit when farthest of are attracted being liener atthe sarie; ous inequalities in the motion of the lecondary planets: Some of these measuratives, however, would take place; inequalitie though the moon of andiburted by the fun had moved of the in a circle concentrical to the earth, and is the plane moon's me of the earth's motion; others depend on the elliptical plained. figure and oblique fituation of the moon's orbit. One of the former is, that the moon does not describe equal spaces in equal times, but is continually accelerated as the passes from the quarter to the new or full, and is retarded again by the like degrees in returning from the new and full to the next quarter: but here we consider not so much the absolute as the apparent. motions of the moon with respect to us. These two. may be distinguished in the following manner: Let S in fig. 123, represent the fun, A the earth moving in its orbit BC, DEFG the moon's orbit, and H the place of the moon in her orbit. Suppose the earth to have moved from A to I. Because it has been shown that the moon partakes of all the progressive motion of the earth, and likewise that the sun attracts both the earth and moon equally when they are at the fame distance from it, or that the mean action of the sun upon the moon is equal to its action upon the earth : we must therefore consider the moon as carrying about with it the moon's orbit: so that when the earth is removed from A to I, the moon's orbit shall likewife.

221

Motions of be removed from its fomer fituation into that denoted the Secon- by KLMN. But now the earth being in I, if the dary Pla- moon were found in O, so that OI should be parallel to HA, though the moon would really have moved from H to O, yet it would not have appeared to a spectator upon the earth to have moved at all, because the earth has moved as much as itself; so that the moon would full appear in the same place with respect to the fixed stars. But if the moon be observed in P, it will then appear to have moved, its apparent motion being measured by the angle under OIP. And if the angle under PIS he less than the angle under HAS, the moon will have approached nearer its conjunction with the fun. Now, to explain particularly the incquality of the moon's motion already mentioned, let S in fig. 124, represent the fun, A the earth, BCDE the moon's orbit, C the place of the moon when in the latter quarter. Here it will be nearly at the same distance from the sun as the earth is. In this case, therefore, they will be both equally attracted, the earth in the direction AS, and the moon in that of CS: Whence, as the earth, in moving round the fun, is continually descending towards it, so the moon in this situation mult in any equal portion of time defcend as much; and therefore the position of the line AC in respect of AS, and the change which the moon's motion produces in the angle CAS, will not be altered by the fan : but as foon as the moon is advanced from the quarter toward the new or conjunction, suppose to Cuthe action of the Can upon it will have a different Were the fun action upon the moon here to be applied in the direction GH parallel to AS, if its action on the moon were equal to its action on the enth, no change would be wrought by the fun on the apparent metion of the moon round the earth. But the moon morning a greater impulse in G than the tion Gille yet it would accelerate the description of the space DAG, and cause the angle under GAD to decrease faster than it otherwise would? The fun's action; will have this effect upon account of the obliquity of its direction to that in which the earth attracts the moon. For the moon by this means is drawn by two forces oblique to one another; one drawing from G. towards A, the other from Getowards H: therefore the moon must necessarily be impelled toward D. Again, Because the sun does not act in the direction GH parallel to SA, but in the direction GS oblique to it; the fun's action on the moon will, by reason of this obliquity, farther contribute to the moon's acceleration. Suppose the earth, in any short space of time, would have moved from A to I, if not attracted by the fun, the point I being in the straight line CE, which touches the earth's orbit in A. Suppose the moon in the same time would have moved inher orbit from G. to K, and besides have partook of all the progressive motion of the earth. Then, if KLi be drawn parallel to AI, and taken equal to it, the moon, if not attracted to the fun, would be found in L. But the earth, by the fun's action, is removed from I. Suppose it were moved down to M in the line IMN parallel to SA, and if the moon were attracted but as much, and in the same direction, as the carch is here supposed to be attracted, so as to have descended during the same time in the line LO parala lel also to AS, down as far at P, till LP were equal to Motions of IM, the angle under PMN would be equal to that un- the Sceonder LIN; that is, the moon will appear advanced as dary Pfamuch farther forward than if neither it nor the earth, had been subject to the sun's action. But this is on the supposition that the actions of the fun upon the earth and moon are equal; whereas the moon being acted upon more than the earth, did the fun's action draw the moon in the line LO parallel to AS, it would draw it down to far as to make LP greater than IM, whereby the angle under PMN will be rendered greater than that under LIN. But, moreover, as the fun draws the earth in a direction oblique to IN, the earth will be found in its orbit somewhat short of the point M! Flowever, the moon is attracted by the fun still more out of the line LO than the earth is out of the line IN; therefore this obliquity of the fun's action will yet farther diminish the angle under PMN. Thus the moon at the point G receives an impulse from the sun whereby her motion is accelerated; and the fun producing this effect in every place between the quarter and the conjunction, the moon will move from the quarter with a motion continually more and more accelerated; and therefore, by acquiring from time to time an additional degree of velocity in its orbit, the spaces which are described in equal times by the line drawn from the earth to the moon will not be everywhere equal, but those towards the conjunction will be greater than those towards the quarter. But in the moon's passage from the conjunction D to the next quarter, the fun's action will again retard the moon, till, at the next quarter at E, it be restored to the first velocity which it had in C. When the moon. moves from E to the full, or opposition to the fun in B, it is again accelerated; the deficiency of the fun's action on the moon from what it has upon the earth, producing here the same effect as before the excess of its action.

Let us now confider the moon in Q as moving from E-towards B. Here, if she were attracted by the sun in a direction parallel to AS, yet being acted on less than the earth, as the latter defeends towards the fun, the mosn will in some measure be left behind. Therefore, QF being drawn parallel to SB, a spectator on the earth would fee the moon move as if attracted from the point Q in the direction QF, with a degree of force equal to that whereby the fun's action on the moon falls thort of its action on the earth. But the obliquity of the fun's action has here also an effect. In the time the earth would have moved from A to I without the influence of the fun, let the moon have moved in its orbit from Q to R: Drawing, therefore, RT parallel and equal to AI, the moon, by the motion of its orbit, if not attracted by the fun, must be found in T; and therefore, if attracted in a direction parallel to SA, would be in the line TV parallel to AS; suppose in W. But the moon in Q being farther off the fun than the earth, it will be less attracted; that is, TW will be less than IM; and if the line SM: be prolonged towards X; the angle under XMW will: be less than, XIT. Thus, by the fun's action, the moon's passage from the quarter to the full would be accelerated, if the fun were to act on the earth and moon in a direction parallel to AS; and the obliquity of the fun's action will ftill increase this acceleration :

Motions of For the action of the fun on the moon is oblique to the Secon- the line SA the whole time of the moon's passage from Q to T, and will carry her out of the hne TV towards the earth. Here we suppose the time of the moon's passage from Q to T so short, that it shall not pass beyoud the line SA. The earth will also come a little short of the line IN, as was already mentioned; and from these causes the angle under XMW will be still farther lessened. The moon, in passing from the oppofition B to the next quarter, will be retarded again by the same degrees as it was accelerated before its appulse to the opposition; and thus the moon, by the fun's action upon it, is twice accelerated and twice restored to its first velocity every circuit it makes round the earth; and this inequality of the moon's motion about the earth is called by aftronomers its variation.

283 Effect of Traction in

The next effect of the fun upon the moon is, that the fun's at- it gives the orbit of the latter in the quarters a greater degree of curvature than it would receive from the purts of the earth alone; and, on the contrary, in the conjunction moon's or- and opposition the orbit is less inflected. When the moon is in the conjunction with the fun at D, the latter attracting her more forcibly than it does the earth, the moon is by that means impelled less to the earth than otherwise it would be, and thus the orbit less incurvated: for the power by which the moon is impelled towards the earth being that by which it is infected from a rectilinear course, the less that power is, the his it will be inflected. Again, When the moon is in the opposition in B farther removed from the fun than the earth is, it follows then, that though the earth and moon are both continually descending toward the fun, that is, are drawn by the fun towards itself out of the place they would otherwise move into, yet the moon descends with less velocity than the earth: insomuch that, in any given space of time from its passing the point of opposition, it will have less approached the earth than otherwise it would have done; that is, its orbit, in respect to the earth, will approach nearer to a straight line. Lastly, When the motion is in the quarter in F, and equally distant from the sun as the earth, it was before observed, that they would both descend with equal velocity towards the fun, so as to make no change in the angle FAS; but the length of the line FA must necessarily be shortened. Therefore the moon, in moving from F toward the conjunction with the fun, will be impelled more toward the earth by the fun's action than it would have been by the earth alone, if neither the earth nor the moon had been acted upon by the fun; fo that, by this additional impulse, the orbit is rendered more curve than it otherwise should he. The same effect will also be produced in the other quarter.

Amhird effect of the fun's action, and which follow that just now explained, is, that though the moon undisturbed by the sun might move in a circle, having the earth for its centre, by the fun's action, if the earth were to be in the very middle or centre of the moon's orbit, yet the moon would be nearer the earth at the new and full than in the quarters. This comet near-may at first appear somewhat difficult to be understood, that the moon should come nearest to the earth when earth when it is least attracted by it : yet, upon a little consideration, it will evidently appear to flow from that very acted by cause, because her orbit, in the conjunction and oppo-

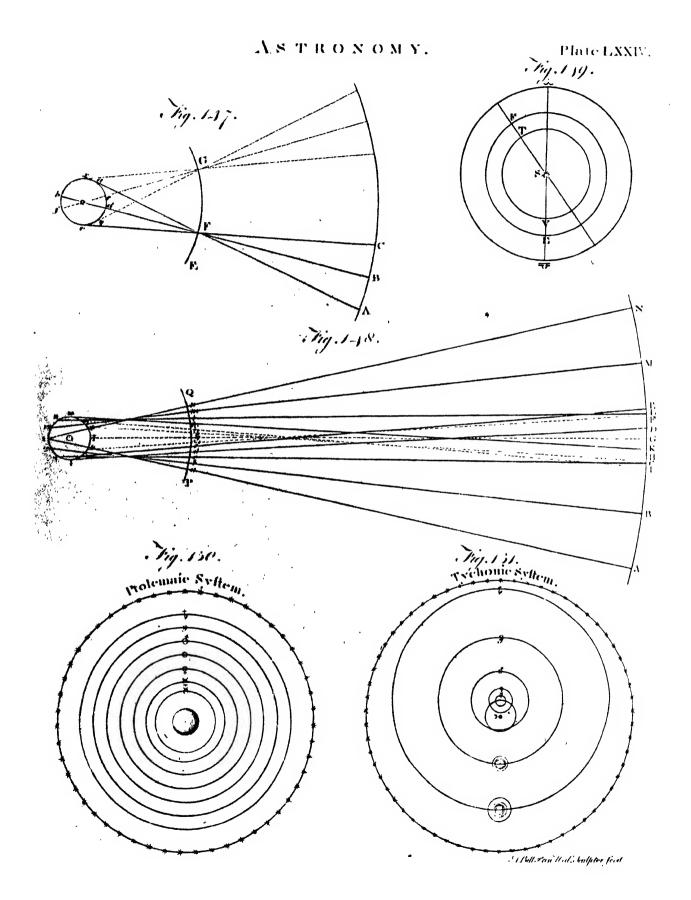

fition, is rendered less curve; for the less curve the or- Motion of bit is, the less will the moon have descended from the the Seconplace it would more into without the action of the dary Plaearth. Now, if the moon were to move from any place without further diffurbance from that action, fince it would proceed on the line touching the orbit in that place, it would continually recede from the earth; and therefore, if the power of the earth upon the moon be fufficient to retain it at the same distance, this diminution of that power will cause the diffance to increase though in a less degree. But, on the other hand, in the quarters, the moon being preffed in a lefs degree towards the earth than by the earth's fingle action, will be made to approach it : so that, in passing from the conjunction or opposition to the quarters, the moon ascends from the earth; and in passing from the quarters to the exposition or conjunction, it descends again, becoming nearer in these last mentioned places than in the other.

All the inequalities we have mentioned are different in degree as the fun is more or less diffant from the earth; being greatest when the earth is in its perihe-lion, and smallest when it is in its aphelion: for in the quarters, the nearer the moon is to the fun the greater is the addition to the earth's action upon it by the power of the fun; and in the conjunction and opposition, the difference between the fun's action upon the earth and upon the moon is likewife to much the great-

This difference in the difference between the earth Caufe of and the fun produces a further effect agen the moon's the dilaramotion; causing her orbit to dilute when left remote tion of the from the Isa, and become greener than when it is be farther diffiance t for it is ground by Sir Line bloom ton, that the action of the sin by which it diministrate the earth's power over the much in the conjugation of opposition, is about twice as great as the addition to the carth's action by the fun in the quarters of that upon the whole, the power of the earth on the mone is diminished by the farm, and therefore is smok dipole nished when that action is throught a but at the earth by its approach to the fun, has its influence leffened, the moon, being less attracted, will gradually recede from the carth ; and as the earth, in its seccis from the hun, recovere by degrees its former power, the orbit of the muon must again contract. Two confequences follow from hence, viz. that the moon will be more remote from the earth when the latter is nearest the fund and also will take up a longer time in performing its revolution through the dilated orbit than through the more contracted.

These irregularities would be produced if the moon without being acted upon unequally by the fun, should describe a perfect circle about the earth and in the plane of its mation; but though neither of these circumitances take place, yet the above-mentioned incqualities occur only with some little variation with regard to the degree of them : but some others are observed to take place from the moon's motion being performed in the manner already described: For, as the moon describes an ellipsis, having the earth in one of its foci, this curve will be subjected to various changes, neither preferving conftantly the fame figure nor polition; and because the plane of this ellipsis is not the same with that of the earth's orbit, it thence follows, that the former will continually change; fo

Moon

Motions of that neither the inclination of the two planes towards the Secon- each other, nor the line in which they interfect, will dary Pla- remain for any length of time unaltered.

286 Action of the fun bit to diange.

As the moon does not move in the fame plane with the earth, the fun is but feldom in the plane of her orbit, viz. only when the line made by the common interfection of the two planes, if produced, will pals causes the through the fun. Thus, let S in fig. 125. denote the plane of the fun, T the earth, ATB the plane of the earth's orbit, CDEF the moon's orbit; the part CDE being raifed above, and the part CFE depressed under, the former. Here the line CE, in which the two planes interfect each other, being continued, passes through the fun in S. When this happens, the action of the fun is directed in the plane of the moon's orbit, and cannot draw her out of this plane, as will evidently appear from an inspection of the figure; but in other cases the obliquity of the sun's action to the plane of the orbit will cause this plane continually to change.

Let us now suppose, in the first place, the line in which the two planes interfect each other to be perpendi ular to the line which joins the earth and fun. f.et T, in fig. 126, 127, 128, 129, represent the earth; S the fun; the plane of the scheme the plane of the earth's orbit, in which both the fun and earth are placed. Let AC be perpendicular to ST, which joins the earth and fun; and let the line AC be that in which the plane of the moon's orbit interfects the orbit of the earth. On the centre T'describe in the plane of the earth's motion the circle ABCD; and in the plane of the moon's orbit describe the circle AECF yone half of which, AEC, will be elevated above the plane of this scheme, and the other half, AFC, se much depressed below it. Suppose then the moon to fat out from the point A in fig. 127, in the direction of the plane AEC. Here the will be continually drawn out of this plane by the action of the . . San ; for this plane AEC, if extended, will not pale through the fun, but above it; so that the fun, by drawing the moon directly toward itself, will force it continually more and more from that plane towards the plane of the earth's motion in which itself is, eaufing it to describe the line AKGHI, which will be convex to the plane AEC, and concave to the plane of the earth's motion. But here this power of the fun, which is faid to draw the moon toward the plane of the earth's motion, must be understood principally of as much only of the fun's action upon the moon as it exceeds the action of the same upon the earth: For suppose the last mentioned figure to be viewed by the eye placed in the plane of that solding, and in the line CTA, on the side A, it will appear as the straight line DTB in fig. 130. and the plane AECF as another straight line FE, and the curve line AKGHI under the form of the line TKGHI. Now it is plain, that the earth and moon being both attracted by the fun, if the fun's action upon both was equally strong, the earth T, and with it the plane AECF, or the line FTE, would be carried towards the fun with as great velocity as the moon, and therefore the moon not drawn out of it by the fun's action, except only from the small obliquity of direction of this action upon the moon to that of the fun's action upon the earth, which arries from the moon being out of the plane of the earth's motion, and is not confiderable: but the action of the fun upon the moon be-· Vol. II. Part II.

ing greater than upon the earth all the time the moon Motions of is nearer to the fun than the earth is, it will be drawn the f confrom the plane AEC, or the line TE, by that excess, dary Plaand made to describe the curve line AGI or TGI. But it is the cultom of aftronomers, instead of considering the moon as moving in fuch a curve line, to refer its motion continually to the plane which touches the true line wherein it moves at the point where at any time the moon is. Thus, when the moon is in the point A, its motion is confidered as being in the plane AEC, in whose direction it then attempts to move; and when in the point K, fig. 127. its motion is referred to the plane which passes through the earth and touches the line AKGHI in the point K. Thus the moon, in passing from A to I, will continually change the plane of her motion in the manner we shall now more particularly explain.

. Let the plane which touches the line AKI in the point K, fig. 127. interfect the plane of the earth's orbit in the line LTM. Then, because the line AKI is concave to the plane ABC, it falls wholly between that plane and the plane which touches it in K; fo that the plane MKL will cut the plane AEC before it meets the plane of the earth's motion, suppose in the line YT, and the point A will fall between K and L. With a radius equal to TY or TL describe the semicircle LYM. Now, to a spectator on the earth, the moon when in A will appear to move in the circle AECF; and when in K, will appear to be moving in the femicircle LYM. The earth's motion is performed in the plane of this scheme; and to a spectator on the earth the fun will always appear to move in that plane. We may therefore refer the apparent motion of the fun to the circle ABCD described in this plane about the earth. But the points where this circle, in which the fun feems to move, interfects the circle in which the moon is feen at any time to move, are called the nodes of the moon's orbit at that time. When Nedes of the moun is feen moving in the circle AECD, the the moun's points A and C are the rodes of the orbit; when the crost appears in the semicircle LYM, then L and M are the nodes. It will now appear, from what has been faid, that while the moon has moved from A to K. one of the nodes has been carried from A to L, and the other as much from C to M. But the motion from A to L and from C to M is backward in regard to the motion of the moon, which is the other way from A to K, and from thence toward C. Again: the angle which the plane wherein the moon at any time appears makes with the plane of the earth's motron, is called the inclination of the moon's orbit at that time: we shall now therefore proceed to show, Inclustion that this inclination of the orbit, when the moon of her is in K, is less than when she was in A: or, that orbit. the plane LYM, which touches the line of the moon's motion in K, makes a less angle with the plane of the earth's motion, or with the circle ABCD, than the plane AEC makes with the same. The semicircle LYM intersects the semicircle AEC in Y, and the arch AY is less than LY, and both together less than half a circle. But it is demonstrated by spheric geometry, that when a triangle is made as here, by three arches of circles AL, AY, and YL, the angle under YAB without the triangle is greater than the angle YLA within, if the two arches AY, YL, taken toge-3 K ther,

Motions of ther, do not amount to a semicircle. If the two arches the Secon- make a complete femicircle, the two angles will be equal; but if the two arches taken together exceed a femicircle, the inner angle YLA is greater than the other. Here then the two arches AY and LY together being less than a semicircle, the angle under ALY is less than the angle under BAE. But from the doctrine of the sphere it is also evident, that the angle under ALY is equal to that in which the plane of the circle LYKM, that is, the plane which touches the line AKGIII in K, is inclined to the plane of the earth's motion ABC; and the angle under BAE is equal to that in which the plane AEC is inclined to the same plane. Therefore the inclinations of the former p'ane is less than that of the latter. Suppose, now, the moon to be advanced to the point G in ng. 128, and in this point to be diffant from its node a quarter part of the whole circle; or, in other words, to be in the nud way between its two nodes. In this onfe the podes will have receded yet more, and the inclimation of the orbit be full more diminished; for suppose the line AKGIII to be touched in the point G by a plane passing through the earth T, let the interfection of this plane with the plane of the earth's riotion be the line WTO, and the line TP its intertection with the plane LKM. In this plane let the circle NGO be described with the semidiameter TP or NT cutting the other circle LKM in P. Now, the line AKGI is convex to the plane LKM which touches it in K; and therefore the plane NGO, which touches it in G, will interfect the other touching plane between G and K, that is, the point P will fall between these two points, and the plane continued to the plane of the earth's motion will pass beyond L; so that the points N and O, or the places of the nodes when the moon is in G, will be faither from A and C than L and M; that is, will have moved farther backward. Besides, the inclination of the plane NGO to the plane of the carth's motion ABC is less than the inclination of the plane LKM to the same; for here also the two arches LP and NP, taken together, are less than a femicircle, each of them being less than a quadrant, as appears, because GN, the diffance of the moon in G from its node N, is here supposed to be a quarter part of a circle. After the moon is passed beyond G, the case is altered; for then these arches will be greater than quarters of a circle; by which means the inclination will be again increased, though the nodes still go on to move the same way. Suppose the moon in H (fig. 129.), and that the plane which touches the line AKGI in H interfects the plane of the earth's motion in the line QTR, and the plane NGO in the line TV, and belides, that the circle QIIR be described in that plane; then, for the same reason as before, the point V will fall between H and G, and the plane RVQ will pass beyond the last plane OVN, causing the points Q and K to fall farther from A and C than N and O. But the arches NV, VQ are each greater than the quarter of a circle; consequently the angle under BQV will be greater than that under BNV. Lastly, When the moon is by this attracthe fun drawn at length into the plane of the s orbit, the node will have receded yet more, and the inclination be so much increased, as to become somewhat more than at first: for the line AKGHI

being convex to all the planes which touch it, the part Motions of HI will wholly fall between the plane QVR and the the Seconplane ABC; fo that the point I will fall between B dary Plaand R; and, drawing ITW, the point W will be farther removed from A than Q. But it 19 evident, that the plane which paffes through the earth T and touches the line AGI in the point I, will cut the plane of the earth's motion ABCD in the line I'TW, and be inclined to the same in the augle under HIB; so that the node which was first in A, after having passed into L, N, and Q, comes at last into the point W, as the node which was at first in C has passed from thence succesfively through the points M, O, and R, to I. But the angle HIB, which is now the inclination of the orbit to the plane of the ecliptic, is manifelly not less than the angle under ECB or EAB, but rather fomething greater. Thus the moon, while it passes from the plane of the earth's motion in the quarter, till it comes again into the same plane, has the nodes of its orbit continually moved backward, and the inclination of it at first diminished till it comes to G in fig. 128. which is near to its conjunction with the fun, but afterwards is increased again almost by the same degrees, till upon the muon's arrival again to the plane of the earth's motion, the inclination of the orbit is restored to something more than its first magnitude, though the difference is not very great, because the points I and C are not far distant from each other.

In like manner, if the moon had departed from the quarter at C, it should have described the curve line CXW in fig. 126, between the planes AFC and ADC, which would be convex to the former planes and concave to the latter; fo that here also the nodes would continually recede, and the melination of the orbit gradually diminish more and store, till the moon arrived near its apposition to the fan in the fact that stam that time the inclination should again increase till it become a little greater than at fast. This will easily appear by considering, that as the action of the sun appear is moon, by exceeding its action upon the centre, drewitt out of the plane AEC towards the sun, while the moon passed from A to I; so during its passage from C to W, the moon being all that time farther from the fun than the earth, it will be attracted less; and the earth, together with the plane AECF, will as it were be drawn from the moon, in fuch a manner, that the path the moon describes shall appear from the earth as it did in the former case by the moon being drawn away.

Such are the changes which the nodes and inclina-Motion of tion of the moon's orbit undergo when the nodes are the nodes in the quarters; but when modes by their motion, explained, and the motion of the fun together, come to be fituated between the quarter and conjunction or opposition, their motion and the change made in the inclination of the orbit are somewhat different .- Let AGH, in fig. 131. be a circle described in the plane of the earth's motion, having the earth in T for its centre, A the point opposite to the sun, and G a sourth part of the circle distant from A. Let the nodes of the moon's orbit be fituated in the line BID, and B the node falling between A, the place where the moon would be in the full, and G the place where she would be in the quarter. Suppose BEDF to be the plane in which the moon attempts to move when it proceeds from the point B: then, because the moon in B is more

Motions of distant from the sun than the earth, it will be less atthe Secon- tracted by the fun, and will not descend towards the fun fo fast as the earth, consequently it will quit the plane BEDF, which is supposed to accompany the earth, and describe the line BIK convex to it, till such time as it comes to the point K, where it will be in the quarter; but from thenceforth being more attracted than the earth, the moon will change its course, and the following part of the path it describes will be concave towards the plane BED or BGD, and continue concave to the plane BGD till it crosses that plane in L, just as in the preceding case. Now, to show that the nodes, while the moon is passing from B to K, will proceed forward, or move the fame way with the moon, and at the fame time the inclination of the orbit will increase when the moon is in the point I, let the line MIN pass through the earth T, and touch the path of the moon in I, cutting the plane of the earth's motion in the line MTN, and the line BED in TO. Because the line BIK is convex to the plane BED, which touches it in B, the plane NIM must cross the plane DEB before it meets the plane COB; and therefore the point M will fall from G towards B; and the node of the moon's orbit being translated from B

> towards M is moved forward. Again: the angle under OMG, which the plane MON makes with the plane BGC, is greater than the angle OBG, which the plane BOD makes with the fame. This appears from what has been already demontrated, because the arches BO and OM are each of them less than the quarter of a circle; and therefore, taken both together and less than a semicircle. But supper, when the most a come to the point K in its quarter, the most will be allowed yet farther forward, and the included of the orbit allo more augmented. Plane which, passing through the earth, touches the passion the moon in the point where the moon is as we have already faid that the custom of ultronomers is. But in the point K no fuch plane can be found: on the contrary, feeing the line of the moon's motion on one fide the point K is convex to the plane BED, and on the other lide concave to the lame, to that no plane can pals through the points T and K, but will cut the line BKL in that point; therefore, instead of such a touching plane, we must make use of PKQ, which is equivalent, and with which the line BKL thall make a less angle than with any other plane; for this does as it were touch the line BK in the point K, fince it cuts it in such a manner that no other plane can be drawn fo as to pais between the line BK and the plane PKQ. But now it is evident, that the point P, or the node, is removed from M towards G, that is, has moved yet farther forward; and it is likewife as manifest, that the angle under KPG, or the inclination of the moon's orbit in the point K, is greater than the angle under IMG for the reason already given.

> After the moon has passed the quarter, her plane being concave to the plane AGCH, the nodes will recede as before till she arrives at the point L; which shows, that, considering the whole time of the moon's passing from B to L, at the end of that time the nodes shall be found to have receded, or to be placed more backward, when the moon is in L than when it was

in B; for the moon takes a longer time in paffing Motions o from K to L than in passing from B to K; and there the Seconfore the nodes continue to recede a longer time than dary Plathey moved forwards; so that their recess mult surmount their advance. In the fame manner, while the moon is in its passage from K to L, the inclination of the orbit shall diminish till the moon come to the point in which it is one quarter part of a circle distant from its node, suppose in the point R; and from that time the inclination will again increase. Since, therefore, the inclination of the orbit increases while the moon is passing from B to K, and diminishes itself again only while the moon is passing from K to R, then augments again while the moon passes from B to L; it thence comes to be much more increased than diminished, and thus will be distinguishably greater when the moon comes to L than when it fets out from B. In like manner, when the moon is passing from L on the other fide the plane AGCH, the node will advance forward as long as the moon is between the point L and the next quarter; but afterwards it will recede till the moon come to pass the plane AGCH again, in the point V between B and A: and because the time between the moon's passing from L to the next quarter is less than the time between that quarter and the moon's coming to the point V, the node will have receded more than it has advanced; fo that the point V will be nearer to A than L is to C. So also the inclination of the orbit, when the moon is in V, will be greater than when the was in L: for this inclination increases all the time the moon is betwixt L and the next quarter, decreasing only when she is passing from this quarter to the mid-way between the two nodes. and from thence increales again during the whole paffage through the other half of the way to the next node.

In this manner we fee, that at every period of the moon the nodes will have receded, and thereby have approached towards a conjunction with the fun: but this will be much forwarded by the motion of the earth, or the apparent motion of the fun lumfelf. In the last scheme the fun will appear to have moved from S towards W. Let us suppose it had appeared to have moved from S to W while the moon's node has receded from B to V; then drawing the line WTX, the arch VX will represent the distance of the line drawn between the nodes from the fun when the moon is in V; whereas the arch BA represented that distance when the moon was in B. This visible motion of the fun is much greater than that of the node; for the fun appears to revolve quite round in one year, while the node is near nineteen in making its revolution. We have also seen, that when the moon was in the quadrature, the inclination of her orbit decreased till the came to the conjunction or opposition, according to the node it fet out from; but that afterwards it again increased till it became at the next node rather greater than at the former. When the node is once removed from the quarter nearer to a conjunction with the fun, the inclination of the moon's orbit, when she comes into the node, is more feufibly greater than it was in the node preceding; the inclination of the orbit by this means more and more increasing till the node comes into conjunction with the fun: at which time it has been shown that the latter has no power to

Motions of change the plane of her orbit. As foon, however, as the Secon- the nodes are got out of conjunction towards the other quarters, they begin to recede as before; but the inclination of the orbit in the appulle of the moon to each fucceeding node is less than at the preceding, till the nodes come again into the quarters. This will appear as follows: Let A, in fig. 132. represent one of the moon's nodes placed between the point of oppolition B and the quarter C. Let the plane ADE pass through the earth T, and touch the path of the moon in A. Let the line AFGH be the path of the moon in her passage from A to H, where the crosses again the plane of the earth's motion. This line will be convex towards the plane ADE, till the moon comes to G, where she is in the quarter; and after this, between G and H, the fame line will be concave towards this plane All the time this line is convex towards the plane ADE, the nodes will recede a sud. on the contrary, move forward when the line in concave towards that plane. But the moon is longer in passing from A to G, and therefore the nodes go back. ward farther than they proceed; and therefore, on the whole, when the moon has arrived at H, the nodes will have receded, that is, the point H will fall between B and E. The inclination of the orbit will decrease till the moon is arrived at the point F in the middle between A and H. Through the passage between F and G the inclination will increase, but decrease again in the remaining part of the passage from G to H, and consequently at H must be less than at A. Similar effects, both with respect to the nodes and inclinations of the orbit, will take place in the following passage of the moon on the other fide of the plane ABEC from H, till it comes over that plane again in 1.

Thus the inclination of the orbit is greatest when the line drawn between the moon's nodes will pass through the fun, and least when this line lies in the quarters; especially if the moon at the same time be in conjunction with the fun, or in the opposition. In the first of these cases the nodes have no motion; in all others, the nodes will each month have receded: and this retrograde motion will be greatest when the nodes are in the quarters, for in that case they will have no progressive motion during the whole month a but in all other cases they at some times go forward, viz. whenever the moon is between either of the querters and the node which is less distant from that quar-

ter than the fourth part of a circle.

We have now only to explain those irregularities of the lunar motion which arise from her motion in an ellipsie. From what has been already faid it appeare, that the earth acts on the moon in the reciprocal duplicate proportion of the distance; therefore the moon, if undiffurbed by the fun, would move round the earth in a true ellipfis, and a line drawn from the earth to the fun would pale over equal spaces in equal times. We have, however, already shown, that this equality is disturbed by the fun, and likewise how the figure of the orbit is changed each month; that the moon is nearer the earth at the new and full, and more remote in the quarters, then it would be without the fun. We must, however, pase by those monthly changes, and spalider the effect which the fun will have in the different Stuations of the axis of the orbit in respect of that luminary. This action varies the force wherewith

the moon is drawn towards the earth. In the quarters Motions of the force of the earth is directly increased by the sun, the Seconbut diminished at the new and full; and in the inter-dary Plamediate places the influence of the earth is fometimes lessened, fometimes assisted, by the action of that lumipary. In these intermediate places, however, between the quarters and the conjunction or opposition, the fun's action is so oblique to that of the earth on the moon, as to produce that alternate acceleration and retardation of her motion so often mentioned. But befides this effect, the power by which the moon attracts the earth towards itielf, will not be at full liberty to and with the same force as if the sun acted not at all on the moon; and this effect of the fun's action, whereby it corroborates or weakens the action of the earth, is here only to be confidered; and by means of this influence it comes to pass, that the power by which the moon is impelled towards the earth is not perfectly is the reciprocal duplicate proportion of the diffance, and of confequence the moon will not describe a perfect offiches. One particular in which the lunar orbit will differ from a perfect elliptical figure, confilts in the places where the motion of the moon is perpendicular to the line drawn from itself to the earth. In an ellipfis, after the moon should have fet out in the direction perpendicular to this line, drawn from itself to the earth, and at age greatest distance from the earth, its motion would again become perpendicular to this line drawn between itself and the earth, and the moon be at its nearest distance from the earth, when it should at its nearest distance from the earth, when it should have performed half its period; after having performed the other half period of its mattern, it would need that come perpendicular to the place which the state and half recovered again its greatest statement, that the moon in its real modern, after fetting but a statement incomes makes more than half a seminated which the moon from itself to the same than half a seminated with the same from itself to the same than the months of the same than the months of the same than the same to the earth, and the former arrise from the minor to the earth, and the former arrive again at its westoft dillance from the earth. At other times the moon will descend to her nearest distance before the bye made half a revolution, and recover again its greatest distance before it has made an entire revolution. The place where the moon is at its greatest distance is called the moon's apogeon, and the place of her nearest distance her perigeon; and this change of place, 292 where the moon comes successively to its greatest di-Apogeon and periods. stance from the earth, is called the motion of the apoge- geon of the en. The manner in which this motion of the apogeon moon, is caused by the sun, comes now to be explained.

Sir Isaac Newton has shown, that if the moon were attracted toward the earth by a composition of two powers, one of which were reciprocally in the duplicate proportion of the diffance from the earth, and the other reciprocally in the triplicate proportion of the same distance; then, though the line described by the moon would not be in reality an ellipsis, yet the moon's motion might be perfectly explained by an ellipsis whose axis should be made to move round the earth: this motion being in consequence, as astronomers express. themselves, that is, the same way as the moon itself

Irregularities ariling to oin the moon's mo tion in an ellipfis.

explained.

294 Motion of apogeon determined.

prop. 44.

Motions of moves, if the moon be attracted by the fum of the two the Secon- powers; but the axis must move in antecedence, or dary Plathe contrary way, if the moon be acted upon by the difference of these forces. We have already explained what is meant by duplicate proportion, namely, that Motion in if three magnitudes, as A, B, and C, are so related that antecedence the second B bears the same proportion to the third C and confe- as the first A bears to the second B: then the proporquence ex- tion of the first A to the third C is the duplicate of the proportion of the first A to the second B. Now Triplicate if a fourth magnitude as D be assumed, to which C proportion shall bear the same proportion as A bears to B, and B to C; then the proportion of A to D is the triplicate of the proportion of A to B.

Let now T (fig. 133, 134.) denote the earth, and the moon's suppose the moon in the point A its apogeon or greatest distance from the earth, moving in the direction AF perpendicular to AB, and acted upon from the earth by two fuch forces as already mentioned. By that power alone, which is reciprocally in the duplicate proportion of the distance, if the moon set out with a proper degree of velocity, the elliplis AMB may be described : but if the moon be acted upon by the fam of the forementioned powers, and her velocity in the point A be augmented in a certain proportion; or if · See New-that velocity be diminished in a certain proportion *, son's Princi- and the moon be acted upon by the difference of those eie, Book I powers; in both these cases the line AE, which shall be described by the moon, shall thus be determined.

be described by the moon, shall thus be determined. Let the point M be that into which the moon would satisfied in any given paint of time, had it moved in the displaced in any given paint of time, had it moved in the displaced in any given which and likewise CTD makes a manuscribe in which while ATM shall bear the make properties to the displacement have been described bears in the displacement that who been described bears in the displacement of the interpretation, as in fig. 133. if the moon be attracted by the fum of the powers; but the contrary way (as in fig. 134.) if by their differenes. Then let the line A B be moved into the poftion CD, and the ellipsis AMB into the situation CND, fo that the point M be translated to L; then the point L shall fall upon the path of the moon AE. Now the angular motion of the line AT, whereby it is removed into the fituation CT, represents the motion of the apogeon; by the means of which the motion of the moon might be fully explained by the ellipsis AMB, if the action of the fun upon it was directed to the centre of the earth, and reciprocally in the triplicate proportion of the moon's distance from it; but that not being fo, the motion of the apogeon will not proceed in the regular manner now described. however, to be observed here, that in the first of the two preceding cafes, where the apogeon moves forward, the whole centripetal power increases faster, with the decrease of distance, than if the entire power were reciprocally in the duplicate proportion of the di-

flance; because one part only is already in that pro-

portion, and the other part, which is added to this to

make up the whole power, increases faster with the

decrease of distance. On the other hand, when the

centripetal power is the difference between these two

bodies, it increases less with the decrease of the di-

stance, than if it were simply in the reciprocal duplicate Motions & proportion of the distance. Therefore, if we choose the Seconto explain the moon's motion by an elliptis, which may dary Piabe done without any fensible error, we may collect in, general, that when the power by which the moon is attracted to the earth, by varying the distance, increafes in a greater than the duplicate proportion of the distance diminished, a motion in consequence must be ascribed to the apogeon; but that when the attraction increases in a smaller proportion than that just mentioned, the apogeon must have given to it a motion in antecedence. It is then observed by Sir Isaac Newton, that the former of these cases obtains when the moon is in the conjunction and opposition, and the latter when the is in the quarters; so that in the former the apogeon moves according to the order of the figns; in the other, the contrary way. But, as has been already mentioned, the diffurbance given to the action of the earth by the fun in the conjunction and opposition, being near twice as great as in the quarters, the apogeon will advance with a greater velocity than recede, and in the compais of a whole revolution of the moon will be carried in consequence.

Sir Isaac shows, in the next place, that when the Inequality line AB coincides with the line that joins the fun and in the moearth, the progressive motion of the apogeon, when tion of the apogeon, the moon is in conjunction or opposition, exceeds the retrograde, in the quadratures, more than in any other fituation of the line AB. On the contrary, when the line AB make right angles with that which joins the earth and fun, the retrograde motion will be more confiderable, nay, is found to great as to exceed the progreshive; so that in this case the apogeon, in the compals of an entire revolution of the moon, is carried in antecedence. Yet from the confiderations already mentioned, the progressive motion exceeds the other; so that, on the whole, the motion of the apogeon is in consequence. The line AB also changes its situation with that which joins the earth and fun by fuch flow degrees, that the inequalities of the motion of the apogeon, arising from this last consideration, are much greater than what arise from the other.

This unfteady motion of the apogeon gives rife to Occasions another inequality in the motion of the moon herfelf, another info that it cannot at all times be explained by the fame equality in ellipfis. For whenever the apogeon moves in confermine the eccen-quence, the motion of the luminary must be referred the moon's to an orbit more eccentric than what the moon would orbit. describe, if the whole power by which the moon was acted upon in its passing from the apogeon changed according to the reciprocal duplicate proportion of its distance from the earth, and by that means the moon did describe an immoveable ellipsis: and when the apogeon moves in antecedence, the moun's motion must be referred to an orbit less eccentric. In the former of the two figures last referred to, the true place of the moon L falls without the orbit AMB, to which its motion is referred: whence the orbit ALE truly described by the moon, is less incurvated in the point A. than is the orbit AMB; therefore this orbit is more oblong, and differs farther from a circle than the ellipfis would, whose curvature in A were equal to that of the line ALB: that is, the proportion of the distance of the earth T from the centre of the ellipsis to its axis, will be greater in AMB than in the other; but

that

No.

otions of that other is the ellipsis which the moon would describe, e Secon- if the power acting upon it in the point A were alterbry Pla- ed in the reciprocal duplicate proportion of the diflance; and confequently the moon being drawn more forcibly toward the earth, it will descend nearer to it. On the other hand, when the apogeon recedes, the power acting on the moon increases with the decrease of distance, in less than the duplicate proportion of the distance; and therefore the moon is less impelled towards the earth, and will not defcend to low. Now, suppose, in the former of these figures, that the apogeon A is in the fituation where it is approaching towards the conjunction or opposition of the fung in this case its progressive motion will be more and more accelerated. Here suppose the moon, after having descended from A through the orbit AE as far as F. where it is come to its nearest distance from the centh, ascends again up the line FG. As the motion of the apogeon is here more and more accelerated, it is plain that the cause of its motion must also be on the crease; that is, the power by which the meon is drawn to the earth, will decrease with the increase of the moon's distance in her ascent from F, in a greater proportion than that wherewith it is increased with the decrease of distance in the moon's descent to it. Confequently the moon will ascend to a greater distance than AT from whence it is descended; therefore the proportion of the greatest distance of the moon to the least is increased. But farther, when the moon again descends, the power will increase yet farther with the decrease of distance than in the last ascent it increased with the augmentation of distance. The moon therefore must descend nearer to the earth than it did before, and the proportion of the greatest distance to the least be yet more increased. Thus, as long as the apogeon is advancing to the conjunction or opposition, the proportion of the greatest distance of the moon from the earth to the least will continually increase; and the clliptical orbit to which the moon's motion is referred will become more and more eccentric. As foon, however, as the apogeon is past the conjunction or oppofition with the fun, its progressive motion abates, and with it the proportion of the greatest distance of the moon from the earth to the least will also diminish: and when the apogeon becomes retrograde, the dimination of this proportion will be still farther continued, watil the apogeon comes into the quarter; from thence this proportion, and the eccentricity of the orbits will increase again. Thus the orbit of the moon is most eccentric when the apogeon is in conjunction with the fun, or in opposition to it, and least of all when the apogeomia in the quarters. These changes in the node that clination of the orbit to the plane of the earth and the continuous and in the eccentricity, are varied like the other inequalities in the motion of the moon, by the different distance of the earth from the fun being greatest when their cause is greatest; that is, when the earth is nearest the fun. Sir Isaac the wton has computed the very quantity of many of That acceleration of the nearer yon's inequalities. mote in thotion which is called the variation, when We must, removes the luminary out of the place in maider the sald otherwise be found, somewhat more rest Stuationegree. If the moon, without diffurbance that luminary, would have described a circle concentri-

cal to the earth, his action will cause her approach Nature and nearer in the conjunction and opposition than in the Motions of quarters, nearly in the proportion of 69 to 70. It has the Coalready been mentioned, that the nodes perform their period in almost 19 years. This has been found by observation; and the computations of Sir Isaac assign to them the same period. The inclination of the moon's orbit, when least, is an angle about one-eighteenth of that which constitutes a right angle; and the difference between the greatest and least inclination is about one-eighteenth of the least inclination, according to our author's computations: which is also agreeable to the general observations of astronomers. The motion of the apogeon and the changes in the eccentricity have not been computed by Sir Isaac.

The fame incomparable geometer shows how, by How to comparing the periods of the motions of the fatellites compute which revolve round Jupiter and Saturn with the pe-the inequariod of our moon round the earth, and the periods of litics of the their planets round the fun with our earth's motion, notions of the motion of those fatellites may be tellites. completed from those of our moon, excepting only the morion of the apogeon; for the writte of those latellites, as far as can be discerned by us at this diffance, appearing little or nothing eccentric, this giotion, as deduced from the moon, must be diminished.

6 4. Of the Mature and Motions of the Comete.

That there bodies are not meteors in our in a manifest, because they allowed set in the lame compet, as the moon and start. It there are not to be a manifest of the moon and start. It there are not to be a more than their inclusives concerning them to be not confirmations that they are not to be the fue's action, he concludes, that they mult necessarily nearer than move about the fun as the planets do : and he proves, Jupiter. that the power of the fun being reciprocally in the duplicate proportion of the distance, every body acted spon by him must either fall directly down, or move about him in one of the conic fections; viz. either the ellipsis, parabola, or hyperbola. If a body which defcends towards the fun as low as the orbit of any planet, move with a swifter motion than the planet, it will describe an orbit of a more oblong figure than that of the planet, and have at least a longer axis. The velocity of the body may be so great, that it shall move in a parabola, fo that having once passed the fun, it shall ascend for ever without returning, though the sun will still continue in the focus of that parabola; and with a velocity fill greater, they will move in an hyperbola. It is, however, most probable, that the comets move in very eccentric ellipses, such as represented in fig. 137. where S represents the fun, C the comet, and ABDE its orbit; wherein the distance of S and D far exceeds that of S and A. Hence those bodies are sometimes found at a moderate distance from the sun, and appear within

Nature and within the planetary regions; at other times they af-Motions of cend to vast distances, far beyond the orbit of Saturn, the Comets and thus become invisible.

That the comets do move in this manner is proved They move by our author from computations built upon the obwe ecentric fervations made by many attronomers. These computations were made by Sir Isaac Newton himself upon the comet which appeared toward the latter end of the year 1680 and beginning of 1681, and the same were

profecuted more at large by Dr Halley upon this and other comets. They depend on this principle, that the eccentricity of the orbits of the comets is so great, that if they are really elliptical, yet that part of them which comes under our view approaches fo near to a parabola that they may be taken for fuch without any fenfible error, as in the foregoing figure the parabola FAG, in the lower part of it about A, differs very little from

How to the ellipsis DEAB; on which foundation Sir Haac calculate the motion teaches a method of finding the parabola in which any of a comet. comet moves, by three observations made upon it in

that part of its orbit where it agrees nearest with a parabola: and this theory is confirmed by aftronomical obfervations; for the places of the comets may thus be computed as exactly as those of the primary planets. Our author afterwards shows how to make use of any small deviation from the parabola which may be observed, to determine whether the orbits of the comets be elliptical or not 4 and thus to know whether or not the fame co-

or not, and thus to know whether as not the same comet returns at different scaling. On examining by this rule the comet of 1680, he louised its orbit to agree since exactly with an ellipsit that a parabola, though the afficient of very occasion. It is it cannot perform its resultation in soo perfect. On this Dr. Halley observed, the harrifor is made in this proof a nomet with a similar phase of a made in this proof of a nomet with a similar phase of the made because there several times because the made because the death of Julius Cassar; and so is appreciate heavished at the laterval of 575 ways, the same concluding with the year 1680. He therefore consisted this motion of this comet to be in high to occasion a first, shat a could not return in less

and to coccitite arbit, that it could not return in left than 175 years a which computations agree yet more

perfectly with the observations made on this comet than any parabolic orbit will do. To compare together different appearances of the fame comet, is indeed the only method of discovering with certainty the form of its orbit; for it is impossible to discover the form of one so exceedingly eccentric from observations taken in a small part of it. Sir Isaae Newton therefore proposes to com-

pare the orbits, on the supposition that they are parabolical, of such comets as appear at different times; for if we find the same orbit described by a comet at different times, in all probability it will be the same comet that describes it. Here he remarks from Dr Halley, that the same orbit very nearly agrees to two appear-

ances of a comet about the space of 75 years distance; so that if these two appearances were really of the same comet, the transverse axis of its orbit would be 18 times that of the axis of the earth's orbit; and therefore,

when at its greatest distance from the sun, this comet would be removed not less than 35 times the mean distance of the earth from the same luminary.

Even this is the least distance assigned by our author to any comet in its greatest elongation from the sun; and on the foundation of Dr Halley's computations it was expected in the year 1758 or 1759.

The Astronomer Royal advertises us of the ex. Nature and pected return of the comet of 1532 and 1661, in the Motions of latter end of the year 1788, or beginning of 1789, in the Comerathe following particulars:

"The elements of the orbits of the comets observed by Appian in 1532, and by Hevelius in 1661, are so much alike, as to have induced Mr Halley to suppose them to be one and the fame comet; and astronomers fince have joined in the fame opinion. Hence it should return to its perihelium the 27th of April 1789. But from the diffurbances of the planets, it will probably come a few months fooner. It will first be feen in the fouthern parts of the heavens, if any astronomers should watch for it in situations near the line, or in fouthern climates, in the course of the year 1788, and probably not before the month of September. Aftronomers who may happen to be in those parts will be enabled to direct their telescopes for discovering it as early as possible, by being furnished with the following elements of its orbit:

The perihelium distance Place of ascending node Inclination of the orbit to the ecliptic 28 24° 18' - 32° 36′ Perihelium forwarder in the orbit than

the ascending node Time of the perihelium in the latter end of the year 1788, or beginning of 1789. Its motion is direct. If it should come to its perihelium on January 1. 1789, it might be feen in the fouthern parts of the world with a good achromatic telescope about the middle of September, towards the middle of Pifes, with 55° fouth latitude and 53 fouth declination."

Sir Isaac Newton observes, that as the great eccentricity of the orbits of comets renders them very liable to be disturbed by the attraction of the planets and other comets, it is probably to prevent too great disturbances from these, that while all the planets revolve nearly in the same plane, the comets are disposed in very different ones, and disposed all over the heavens; that when in their greatest distance from the fun, and moving flowest, they might be removed as far as possible out of the reach of each other's action. The same end is likewise answered in these comets, which by moving flowest in the aphelion or remotest distance from the fun, descend nearest to it by placing their aphelion at the greatest height from the fun. See more on the subject of comets by Sir Isaac, Sect. III. No 169.

§ 5. Of the Bodies of the Sun and Planets, with the Method of computing the Quantity of Matter they con-

Our author having proved, as has been related, Attractive that the primary planets and comets are retained in power their orbits by a power directed towards the fun, and diffused that the secondaries are also retained by a power of throughout the like kind directed to the centre of their primaries, the fubproceeds next to demonstrate that the same power is matter. diffuled through their whole substance, and inherent in every particle. For this purpole he shows first, that each of the heavenly bedies attracts the rest and other bodies with fuch different degrees of force, as that the force of the same attracting body is exerted on others exactly in proportion to the quantity of matter contained in the body attracted. The first proof of this he brings from experiments made on bodies here on

earth.

303

matter.

Of the Bo- earth. The power by which the moon is influenced alies of the has been already shown to be the same with that which we call gravity, Now, one of the effects of the principle of gravity is, that all bodies defeend by this force from equal heights in equal times. This was taken Properties notice of long ago; and particular methods have been of gravity invented to show, that the only cause why some bodemonstra- dies were observed to fall in a shorter time than others ted by pen- was the refiftance of the air. As these methods, however, have been found liable to fome uncertainty, Sir Isaac Newton had recourse to experiments made on pendulums. These vibrate by the same power which makes heavy bodies fall to the ground; but if the ball of any pendulum of the fame length with another were more or less attracted in proportion to the quantity of folid matter it contains, that pendulum must then vibrate faster or slower than the other. Now the worktions of pendulums continue for a long time, and the number of vibrations they make may be easily determined without any fuspicion of error; fo that this experiment may be extended to what exactness we please : and Sir Ifaac affures us, that he examined in this way several substances, as gold, filver, lead, glass, fand, common falt, wood, water, and wheat; in all which he found not the least deviation from the theory," tho." he made the experiment in fuch a manner, that in bodies of the same weight, a difference in the quantity of their matter less than the thousandth part of the whole would have discovered itself. It appears, therefore, that all bodies are made to descend here by the power of gravity with the same degree of swiftness. This defcent has already been determined at 16th feet in a fecond from the beginning of their fall. It has also been observed, that if any terrestrial body could be conveyed as high up as the moon, it would descend with the very same degree of velocity with which the moon is attracted toward the earth; and therefore that the power of the earth upon the moon bears the same proportion it would have upon those bodies at the fame distance as the quantity of matter in the moon bears to the quantity in those bodies. Thus the affertion is Attraction proved in the earth, that its power on every body it proportion-attracts is, at the fame distance from the earth, proporquantity of tional to the quantity of folid matter in the body afted upon. As to the fun, it has been shown, that the power of his action upon the same primary planet is reciprocally in the duplicate proportion of its diffance: and that the power of the fun decreases throughout in the same proportion, is testified by the motion of the planets traverling the whole planetary region. This proves, that if any planet was removed from the fun to any distance whatever, the degree of its acceleration towards the fun would yet be reciprocally in the duplicate proportion of their distance. But it has already been proved, that the degree of acceleration given to the planets by the fun is reciprocally in the duplicate proportion of their respective distances; all which, compared together, puts it out of doubt, that the power of the fun upon any planet removed into the place of any other, would give it the same velocity of descent as it gives that other; and consequently that the fun's action upon different planets at the same distance would be proportionable to the quantity of matter in each. It has likewife been shown, that the sun attracts the pri-

the same distance, in such a manner as to communicate Of the Bo to both the fame degree of velocity; and therefore the dies of the force wherewith the fun acts on the secondary planet Planets, bears the fame proportion to the force wherewith it, attracts the primary, as the quantity of matter in the fecondary planet bears to the quantity of matter in the primary. This property therefore is found in the futr with regard to both kinds of planets; fo that he possesfes the same quality found in the earth, viz. that of acting on bodies with a degree of force proportional to the

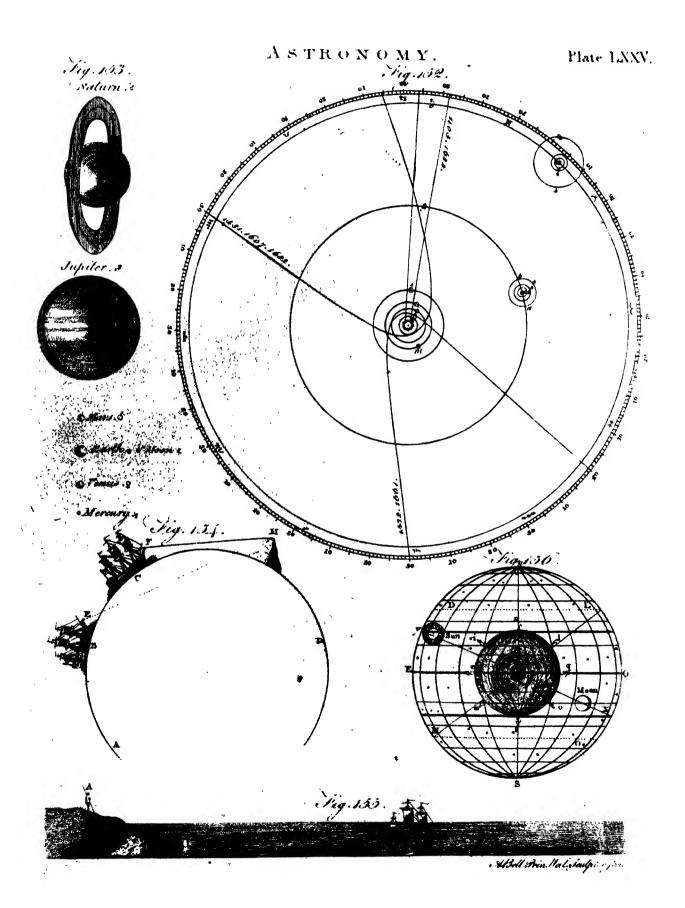

quantity of matter they contain.

This point being granted, it is hardly to be suppofed that the power of attraction with which the other planets are endowed, should be different from that of the earth, if we confider the similitude of these bodies. and that it does not in this respect, is farther evident from the fatellises of Saturn and Jupiter, which are attracted according to this law; that is, in the fame proportion to their distances that their primaries are attracted by the fun. So that what has been concluded of the fun in relation to the primary planets, may be justly concluded of those primaries in respect to their fecondaries; and in confequence of that likewife in regard to all other bodies, viz. that therewill attract every other body in proportion to the quantity of fohid matter it contains. Hence it follows, that this actraction extends itself to every particle of matter in the attracted body, and that no portion of matter is exempted from the influence of thele-bodies to which this attractive power has been proved to belong.

this attractive power has been proved to belong.

Here we may remark, that the attractive power Attraction both of the fun and planter appears to be the family is not equally all: for it acts in each is the fame proportion as all abolis distance, and in the fame mainter acts alike upon grain in the uniparticle of matter. This power; therefore, a fine line were, and planter is not of a different manuscriping in the power of gravity in the careful; and this analysis the power of gravity in the careful; and this analysis in power, that the attraction power longed in this half planter belongs likewife to every part of those is and that their respective powers upon the careful and align the power of the careful at the force with which they we composed at for inflance, that the force with which the careful at. for inflance, that the force with which the careh attracts the moon, is to the force with which the fun would attract it at the fame diffance, as the quantity of folid matter in the earth is to that in the fun.

Before we proceed to a full proof of these affertions, it will be necessary to show that the third law of motion, viz. That action is equal to reaction, holds good in attractive powers as well as in any other. The most remarkable force of this kind with which we are acquainted, next to that of gravity, is the attraction the loadstone has for iron. Now, if a loadstone and piece of iron were both made to fwim on water, both of them would move towards each other, and thus the attraction would be shown to be mutual; and when they meet, they will mutually ftop each other; which shows that their velocities are reciprocally proportioned to the quantities of folid matter in each; and that by the Rone's attracting the iron, it receives as much motion itself in the strict philosophic sense of the word, as it communicates to the iron: for it is proved from experiments on the percuffion of bodies, that if two meet with velocities reciprocally proportional to their respective bodies, they will be stopped by the concourse, unless they meet with some other velocity, or their elasti-

306

Why the

rommon

centre of

gravity.

law.

Of the Bo- city put them into fresh motion. Hitherto, however, dies of the for the fake of brevity, in speaking of these forces, we Sun and have ascribed them to the body which is least moved; as when we called the power which exerts itself between the fun and planets, the attractive power of the fun; but to speak more correctly, we should rather call this power in any case the force which acts between the fun and earth, between the earth and moon, &c. for both the bodies are moved by the power acting between them, in the same manner as when two bodies are tied together by a rope, if that should shrink by being wet or otherwise, and thereby cause the bodies to approach; by drawing both, it will communicate to both the same degree of motion, and cause them to approach each other with velocities proportional to their quantities of matter. From this mutual action fun and plat of the fun and planets upon each other, it follows, as nete revolve has been already mentioned, that they both revolve about their about their common centre of gravity. Thus let A (in fig. 136.) represent the sun, B a planet, and C their common centre of gravity. If these bodies were once at reft, they would directly approach each other by their mutual attraction, and that with fuch velocities, that their common centre of gravity would zemain at reft, and they would meet in that point. Were the planet B to receive an impulse, as in the direction DE, this would prevent the two bodies from falling together; but their common centre of gravity would be put into motion to the direction of the line CF, equidifient from BE. In this case Sir Isaac Newton proves, that the fun and planet would describe round their common searce of gravity fimilar orbits, while that centre would proceed with an uniform velocity in the loss CI, and so the lystem of the two bodies would enter an with the centre of gravity without end. It waster to keep the system in the same place, it is negative, that when the planet received its impute so the mental and IE, the land hould receive such mother the equiversions, to is to keep the centre of gravity C without say motion in Which cale it would

always remain fixed. Thus we may understand in what manner the action between the fun and planets is mutual. It has also been shown, that the power which acts between the fun and primary planets is altogether of the fame nature with that which acts between the fecondary planets and their primaries, or which acts between the earth and bodies near its furface. It has also been already proved, that in different planets the force of the fun's action upon each at the same distance would be proportional to the quantity of folid matter contained in the planet: therefore the reaction of the planet on the fun at the same distance, or the motion which he would receive from each planet, would also be proportional to the quantity of matter in the planet; that is, these planets, at the same distance, would act on the same body, with degrees of strength proportioned to the quantity of folid matter contained in each.

307 In the next place, our author deduces from the prin-The imaliest particles ciples above demonstrated, that each of the particles of matter out of which the fun, moon, and planets, are formed, attract each exert their power of gravitation by the same law, and other acbodies they compose. For this purpose, he first de-Vol. II. Part II. the fame

monstrates, that if a globe were compounded of parti- Of the Be cles which will attract the particles of any other body dies of reciprocally in the duplicate proportion of their diflances, the whole globe will attract the fame in the reciprocal duplicate proportion of their distances from the centre of the globe, provided it be of equal density throughout. Hence also he deduces the reverse; that if a globe acts upon distant bodies by the law just now specified, and the power of the globe be derived from its being composed of attracting particles, each of these will attract after the same proportion. The manner of deducing this is as follows: The globe is supposed to act upon the particles of a body without it confiantly in the reciprocal duplicate proportion of their diffances from the centre; and therefore, at the fame distance from the globe, on which side soever the body be placed, the globe will act equally upon it. Now because if the particles of which the globe is composed acted upon those without in the reciprocal duplicate proportion of their diffances, the whole globe would act upon them in the same manner as it does; Micrefore, if the particles of the globe have not all of them that property, some must act stronger than in that proportion, whilst others act weaker: and if this be the condition of the globe, it is plain, that when the body attracted is in such a fituation in respect of the globe, that the greater number of the strongest particles are nearest to it, the body will be more forcibly attracted than when, by turning the globe about, the greater quantity of weak particles should be nearest. though the distance of the body should remain the fame from the centre of the globe; which is contrary to what was at first remarked, that the globe acts equally on all fides.

It is further deduced from these propositions, that if all the particles of one globe attract all the particles of another in the proportion already mentioned, the attracting globe will act upon the other in the fame proportion to the diffance between the centre of the globe which attracts, and the centre of that which is attracted: and further, that the proportion holds true, though either or both of the globes be composed of diffimilar parts, fome rarer, and fome more denfe; prowided only, that all the parts in the fame globe, equally diffant from the centre, be homogeneous, and likewife if both globes attract each other.

Thus has our author shown that this power in the Attraction great bodies of the universe is derived from the same an univerbeing lodged in every particle of the matter which fal property composes them; and consequently that it is no less of matter. than universal in matter, though the power be too minute to produce any vitible effects on the small bodies with which we are conversant, by their action on one another. In the fixed flars indeed we have no particular proof that they have this power, as we find no appearance to demonstrate that they either act or are acted upon by it. But fince this power is found to belong to all bodies whereon we can make observation, and we find that it is not to be altered by any change in the shape of bodies, but accompanies them in every form, without diminution, remaining ever proportional to the quantity of folid matter in each; such a power must without doubt universally belong to matter.

All

Of the Bodies of the Sun and Planets.

sany of the planets.

All this naturally follows from a confideration of the phenomena of those planets which have secondaries revolving about them. By the times in which thefe satellites perform their revolutions, compared with their distances from their respective primaries, the pro-How to de-portion between the power with which one primary atermine the tracts his fatellites and the force with which any other attracts his, will be known; and the proportion of the power with which any planet attracts his secondary to the power with which it attracts a body at its furface,

is found by comparing the distance of the secondary planet from the centre of the primary to the distance of the primary planet's furface from the fame: and from hence is deduced the proportion between the power of gravity upon the furface of one planet to the gravity upon the furface of another. By the like method of comparing the periodical time of a primary planet about the fun with the revolution of a fatellite about its primary, may be found the proportion of gravity or of the weight of any body on the furface of the fun, to the gravity or to the weight of the fame body upon the furface of the planet which carries about the fatellite. By computations of this kind it is found, that the weight of any body on the surface of the sun will be about 23 times as great as on the furface of the earth; about 10 times as great as on the furface of Jupiter; and near 19 times as great as on Satura. The quantity of matter contained in each of these bodies is proportional to the power it has upon a body at a given distance. Thus it is found, that the fun contains 1067 times as much matter as Jupiter; Jupiter 1587 times as much as the earth, and 27 times as much as Saturn. The diameter of the fun, according to the data with which Sir Isaac Newton was furnished, was calculated at 92 times, that of Jupiter about 9 times and that of Saturn about 7 times as large as the

310 Denfities of

diameter of the earth. By comparing the quantities of matter in each of the heaven- these bodies with their respective magnitudes, their denbodies fities are likewife eafily discovered; the density of every body being measured by the quantity of matter contained under the same bulk. Thus the earth is found 41 times more dense than Jupiter, while Saturn has only between two-thirds and three-fourths of the denfity of the latter, and the fun has only one-fourth part of the density of the earth. From all this our author draws the following conclusions, viz. that the fun is rarefied by its great heat; and of the three planets abovementioned, the most dense is that nearest the sun. This it was highly reasonable to expect, the densest bodies requiring the greatest heat to agreate and keep their parts in motion; as, on the contrary, the planets which more rare would be rendered unfit for their office the intense heat to which the denser are exposed. the waters of our feas, if removed to the distance of Saturn, would remain perpetually frozen, and at Mercury would constantly boil. The densities of the planets Mars, Venus, Mercury, and the Georgium Sidus, se they are not attended with planets on which many observations have been made, cannot be ascertained. From analogy, however, we ought to conclude, that the inferior planets, Venus and Mercury, are more denfe than the earth, Mars more rare, and the Georgiam Sidus much more rare, than any of the rest.

SECT. V. The Newtonian Doctrine applied more par-ticularly to the Explication of the Celefical Pheno-

Particular.

From the general account of those laws by which the universe is upheld, we now proceed to give an explanation of the particular parts of which it is composed. Those which are most exposed to our researches. besides the earth we inhabit, are the Sun, Moor. Mercury, Venus, Mars, Jupiter, Saturn, and the Georgium Sidus (see fig. 119.) The sun, an immense globe of fire, is fituated near the centre of the fystem, round which he turns by a small and irregular motion, according as the common centre of gravity betwixt him and the planets, which is the true centre of the fystem, varies by their different positions on this or that side of him. All the planets move round this common centre of gravity together with the fun; but the latter, by reason of his vast bulk, is so near the true centre, that the motions of the celestial bodies are by astronomers always referred to the centre of the fun as the point round which they are directed. The motions of all of them are performed the same way, viz. from west to east: and some comets have been observed to move also in this way, though the motion of others has been directly contrary. This motion, from west to east, is said to be in the order of the figus, or in confequence, as has been already mentioned, with regard to the moon; while that from east to west is in unteredence, or contrary to the order of the figns. Though all of them, however, revolve round the fun, their motions, as we have already observed, are not in the same plane, but inclined to one another by small angles ; and the way in which we compute this inclination is by confidering the orbit of the earth as a flandard, and calculating the angle which each of their orbits makes with it.

To a spectator placed in the sun, all the planets Heliocenwould appear to describe circles annually in the heatric circles vens; for though their motions are really elliptical, of the plathe eccentricity is fo small, that the difference between ners. them and true circles is not eafily perceived even on earth; and at the fun, whether great or small, it would entirely vanish. These circles, which in such a situation would appear to be annually described among the fixed flars, are called the beliocentric circles of the planets; and if we suppose the orbits of the planets to be extended to the extreme bounds of the creation, they would describe among the fixed stars those circles just mentioned. To a spectator in the sun, the comets, though moving in the most eccentric orbits, would also appear to describe circles in the heavens; for though their orbits are in reality very long ellipses, the planes of them extended to the heavens would mark a great circle thereon, whereof the eye would be the centre; only, as the real motion is in an ellipsis, the body would appear to move much more flowly in some part of the circle than another, and to differ exceffively inmagnitude. To an inhabitant of any planet, however, the fun appears to go round in its own heliocentric circle, or to describe in the heavens that same curve which the planet would appear to do if feen from the fun. Thus (fig. 137.), when the earth is at a, if

Particular we draw a line from a through the sun at S, the point Explication G, in the sphere of the heavens where the line termiof the Ue-nates, is the place where the fun then appears to an noniena. inhabitant of the earth. In a month's time the earth will be got from a to b; draw a line then through the fun, and its extremity at H will point out its apparent place at that time. In like manner, if we draw lines from the earth in the twelve several situations in which it is represented for the twelve months of the year, the fun's apparent place will be found as above, and so it would be found by a spectator placed in Venus or any other planet.

Ecliptic, why fo named.

The heliocentric circle of the earth is called the ecliptic, because eclipses of the sun or moon can only. happen when the latter is in or near it, as will afterwards be more particularly explained. By some ancient writers it has been called the circle of the fun, or the oblique circle, because it cuts the equator at oblique angles. It is also called by Ptolemy the circle which passes through the midst of the animals; because the twelve constellations through which it passes were anciently all represented by animals, or parts of them, though now the balance is introduced in place of the claws of the scorpion. For this reason, a belt or hoop taken in the concave sphere of the heavens about 10 degrees on each fide of the ecliptic is called the sodiac, from a Greek word which signifies an animal; and the confiellations through which the ecliptic is drawn are called the constellations of the zodiac.

How to determine the fun's place.

Zodiac.

Though the fun, as we have faid, apparently goes round the earth annually in the circle just mentioned, we cannot determine his place by mere inspection as we can do that of any of the other heavenly bodies : for the fixed flars are the only marks by which we can determine the places of any of the celettial bodies, and the superior brightness of the sun renders them totally invilible, except in the time of a great ecliple, when his light is for a time totally obscured. But though we cannot know the place of the fun directly, it is eafily found from a knowledge of those fixed stars which are opposite to him. Thus, in fig. 137. suppose it the time of the year in which the earth is at g, if we know that the point G is then diametrically opposite to the fun, we know that A, its opposite, is the sun's place, and consequently, by finding places throughout the year diametrically opposite to the sun, as GHIKLM ABCDEF, we may be affured that in these times the sun's place was in the points ABCDEFGHIKLM. The point of the heavens diametrically opposite to the fun may be known every night at twelve o'clock when the stars are visible; for the star which has an elevation. above the horizon at that time equal to the fun's depreffion below it, is directly opposite to him.

Latitude,

The ecliptic being thus found, the latitude of the declination, moon or any far is counted by its distance from the ecliptic, as the latitude of places on earth is counted by their distances from the equator; and is marked upon circles drawn through the pole of the ecliptic, and perpendicular to its plane, as the latitude of places is marked on one of the meridians of a terrestrial globe. These are called circles of latitude, and each of them is supposed to divide the celestial concave into two equal hemispheres; and the declination of any celeftial body is its deviction from the ecliptic towards

the celestial equator perpendicular to that of the Particular Explication of the Ce-

The latitude of any planetis either heliocentric or geo-leftial Phecentric. The heliocentric latitude is its distance from the nomena. ecliptic as feen from the fun, and its geocentric as feen from the earth, and is considerably different from the former. With the fixed stars indeed it is otherwise; for their distance is so vast that the whole diameter of the earth's orbit is but a point in comparison with it. For this reason, whatever part of its orbit the carth may be in, the fixed flars always appear to keep thefame place; but with respect to the planets, the orbit of the earth, or magnus orbis, as it has fometimes been called, bears a very confiderable proportion, excepting only to the Georgium Sidus, of whose distance the diameter of the earth's orbit forms little more than a tenth part; and therefore all calculations with regard to that ftar are much more difficult than the reft. The apparent place of the planets therefore are confiderably altered by the earth's change of place as well as by their own motions; fo that though a planet should stand still for a whole year, it would nevertheless appear to us to describe a circle round the heavens, as in that space of time we would have been carried by the earth round the fun, and have continually taken a view of it from different stations. As the orbits of the planets are inclined in different angles to the ecliptic, it thence happens, that the heliocentric latitude of any planet is almost always different from its geocentric latitude. Thus, let AB, fig. 138 be the orbitrof the earth, CD the orbit of Venus, viewed with the eye in their common fection, wherein they appear straight lines; let E and F be two opposite points of the ecliptic; and suppose Venus to be in the point C in her utmost north limit. If she were at that time viewed from the fun S, she would appear in the point of the heavens marked H, and her heliocentric latitude is then FH; but if viewed from the earth in B, she will appear at g; at which time her heliocentric latitude is FH, and her geocentric only Fg. When at I, her apparent place is at K, her heliocentric latitude FH, and her geocentric FK; but when the earth is at A, her apparent place will then be at G, and her geocentric latitude EG, while her heliocentric is only FH as before.

The two planets, Mercury and Venus, whose orbits How to are included in that of the earth, are called inferior; find the and Mars, Jupiter, Saturn, and the Georgium Sidus, geocentrie whose orbits include that of the earth, are called fupe-latitude of rior; and from the circumstance just mentioned, they planet. must present very different appearances in the heavens, as will afterwards be particularly explained. The geocentric latitude of a fuperior planet may be understood from fig. 139. Let AB be the orbit of the earth, CD that of Mars, both viewed with the eye in their common section continued, by which they appear in straight lines. Let E and F be opposite points of the ecliptic, and suppose Mars to be in the fouth limit at C. If he were at that time viewed from S the centre of the. fun, he would appear in the sphere of the heavens at the point H; in which case his heliocentric latitude would be FH: But when viewed in C from the earth, or from its centre, which in this case is supposed to be the station of the spectator, he will appear to be in different places of the heavens according to the polition of

3 S 2

§ 317 Modes of a planet.

Merticular the earth. When the earth, for instance, is at B, the Explication place of Mars will appear to be at at g, and his geocen-of the Ce-tric latitude will be F g. When the earth is at A, his And the cartin is at A, fils tude FG: and in like manuer, supposing the earth to be in any other part of its orbit, as in I or K, it is eafy to fee, that his apparent places, as well as geocentric latitudes at those times, will be different.

> The two points where the heliocentric circle of any planet cuts the ecliptic, are called its nodes; and that which the planet passes through as it goes into north latitude, is called the afcending node, and is marked thus &; and the opposite to this is called the descending node, and is marked &. A line drawn from one node to the other is called the line of the nodes of the planet, which is the common fection of the plane of the ecliptic, and that of the planet produced on each fide to the fixed Stars.

318 Zodiac and figns explained.

The zodiac, of which we have already given some account, is either aftral or local. The altral is divided into 12 unequal parts, because it contains 12 celestial conftellations, fome of which are larger than others. This continues always invariably the same; because the fame flars now go to the making up of the different constellations as formerly, excepting some small variations to be afterwards explained. The local zodiac is divided into twelve equal parts, each containing 30 degrees, called figns. These are counted i om the point where the equator and ecliptic interfect each other at the time of the vernal equinox; and are denoted by particular marks, according to the apparent annual motion of the fun. See fig. 158. A motion in the heavens in the order of these figns, as from Aries to Taurus, is faid to be a motion in confequence; and fuch are the true motions of all the planets, though their apparent motions are fometimes contrary, and then they are faid to move in antecedence. The local zodiac is not always invariably the fame as to the places of the feveral figns, though the whole always takes up the same place in the heavens, viz. 10 degrees on each fide the ecliptic. The points where the celestial equator cuts into the ecliptic, are found to have a motion in antecedence of about 50 feconds in a year. This change of place of the first point of the ecliptic, from whence the figns are counted, occasions a like change in the figns themselves; which, though scarce sensible for a few years, has now become very confiderable. Thus, fince aftronomy was first cultivated among the Greeks, which is about 2000 years ago, the first point of the ecliptic is removed backward above a whole fign: and though it was then about the middle of the constellation Aries, is now about the middle of Pisces. Notwithstanding this alteration, however, the signs still retain their ancient names and marks. When the zodiac is mentioned by astronomers, the local zodiac is generally meant.

319 Longitude of celestial bodies explained.

The longitude of a phenomenon in the heavens is the number of degrees counted from the first point of A. ries on the ecliptic to the place where a circle of latitude drawn through the phenomenon would cut the ecliptic at right angles. Every phenomenon in the heavens, whether in the zodiac or not, is thus referred to the ecliptic by the circles of latitude, as the longitudes of terrestrial places are referred to the equator by the meridians; and whatever fign the circle of latitude pal-

fee through, the phenomenon is faid to have its place in Particular that fign, though ever fo far distant from it.

Some aftronomical writers have made the local zo- leftial Phodiac invariable; for which purpose they imagine a homena. circle of latitude drawn through the first star of the constellation Aries, marked in Bayer's catalogue by the Greek letter y; and reckon their longitude from the point where that circle cuts the ecliptic. This ftar, from its use, is called the first star of the Ram: and when this method is made use of, the longitude of any phenomenon is faid to be for many fights, degrees, minutes, &c. from the fall flar of the Ram. Thus, in Street's Caroline tables, the longitude of Jupiter's ascending node is two figus cight degrees from the first star of Arics, which is thus marked: Long. 19 & à 1 * 9 25 8°. The common way of reckoning the longitude of a phenomenon is to take or for the first point of the celiptic, and not to number the degrees quite round that circle as a continued feries, but to make a new beginning at the first point of every fign, and to reckon from thence only the length of 30°. When this method is made use of, the longitude of any phenomenon is expressed, by saying it is in such a degree and fuch a minute of a fign: and thus we may express the longitude of the alcending node of Mercury, \$ & \$ 14° 40'; and so of any other. The place of a phenomenon in the heavens is expressed by setting down its longitude and latitude, as is done with places

fituated anywhere on the furface of the earth.

Having thus explained the aftronomical terms com-

monly made use of with respect to the planets, and likewise shown how, from their motions and that of the earth, there must be a considerable variation in their apparent places, as feen from the fun and from the earth; we shall now proceed to a more particular confideration of their phenomena, as derived from a compolition of the two motions jult mentioned, viz., that of the planets in their respective orbits, and that of the earth in the celiptic. Every planet, like the moon, is some-Conjunctimes in conjunction and fometimes in opposition with tions and the fun. Its conjunction is when the geocentric place opposition of the planet is the same with that of the sun; though nets ex an exact or central conjunction can only take place planted. when the line of its nodes passes through the earth, and the planet itself is in one of its nodes at the time. It is however, in general, called a conjunction or oppolition, when the same circle of latitude passes through the fun and planet at the fame time. When the geocentric place of a planet is 90°, or a quarter of a circle from the fun's place, the planet is faid to be in quadra- Afpede of ture or in a quartile aspect with the sun; and these the planet terms are used in a like sense when applied to any two of the heavenly bodies. Thus the fun and moon, or the moon and any planet, or any two planets, may be in

Conjunction, Opposi ion. Quadrature. Trine. Sextile. C3 The afpects were supposed to influence the affairs of mankind; and many conclusions drawn from them too abfurd to be mentioned here, and now indeed almost entirely buried in oblivion.

conjunction, opposition, or quadrature. Besides these,

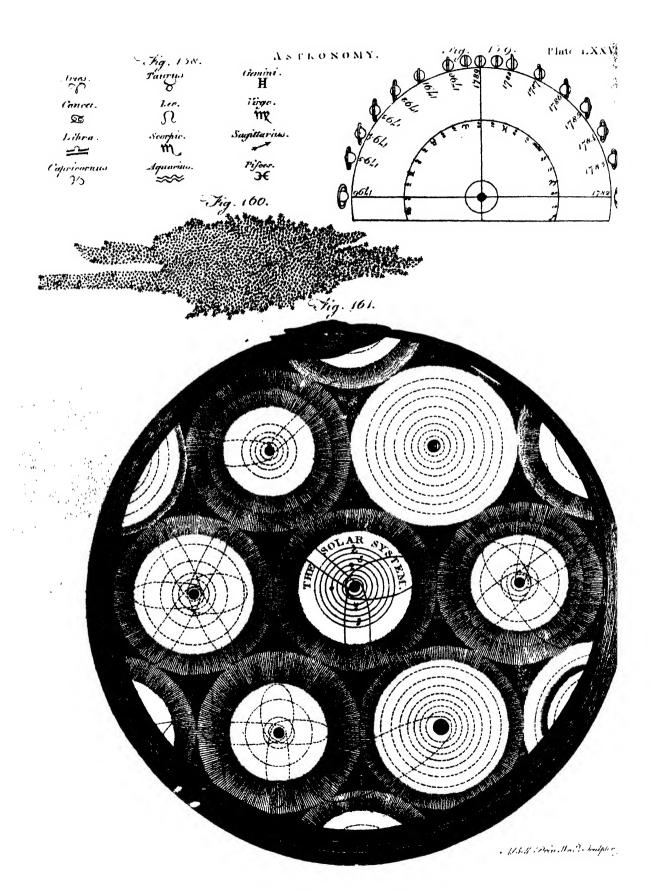

the ancients reckoned other two aspects, the trine and

the fextile; the former when the bodies were distant

120°, and the latter when only half that distance. These

aspects are marked thus:

The

The inferior planets have two kinds of conjunction Explication with the fun; one in the inferior part of their femiof the Ce-circles, where they are nearer to the earth than the nomena, fun; the other in the superior cort, where they are farther off. In the former, the planet is between the earth and the fun; and in the latter, the fun is between the earth and planet. The inferior planets can never be in opposition to the fun, nor even appear at a great distance from him. The length they go is called their elongation. Thus, in fig. 140. let OPQRT be part of the ccliptic; S the fun; and the three circles Geocentric roundhim, the orbits of Mercury, Venus, and the Earth. places, &c Suppose the earth to be at A, the sun's geocentric of the infer place will be at Q. If Mercury be then at I, his rior planets, geocentric place is likewife at Q; fo that he is in conjunction with the fun in his inferior femicircle: if at M, his geocentric place is likewise at Q; so that he is in conjunction in his superior semicircle. In like manner, Venus at E is in conjunction in her inferior femicircle, at G in her superior: but if we suppose the earth to be at A, and Venus at H, her geocentric place is T, and her elongation QT, which in this figure is the greatest possible; for this always takes place when a straight line from the earth touches the orbit of the planet, as is evident from the figure; that is, provided the planet be in its aphelion at the time. Thus the greatest possible elongation of Mercury is QP when he is in his aphelion at L; and the quantity of this is found by aftronomical observations to be about 28 degrees, that of Venus about 48. The inferior planets in their elongations are fometimes eastward and fometimes westward of the sun; in the former case they ap-

prevent him from being often taken notice of; but the largeness and beauty of Venus have made her, in all ages, celebrated as the evening and morning star. Direct and

The irregular apparent motion of the planets has retrograde been already taken notice of; sometimes going forthe planets ward, fometimes backward, and fometimes appearing explained, to stand still for a little. These different conditions are by astronomers called direct, retrograde, and station-Were they to be viewed from the fun, they would always appear direct, as has been already shown; but when viewed from the earth, the inferior planets appear direct while moving in their upper semicircles, and retrograde when in their lower ones. Thus, in fig. 140, suppose the earth at rest at A, while Mercury is going on in his orbit from N to I; from I to L his motion appears to an observer at A to be retrograde, or contrary to the order of the figns, namely, from R to Q and from Q to P; but when in that part of his orbit which lies between L and N, his motion appears

pear in the evening, and in the latter in the morning. The smallness of Mercury and his nearness to the sun

direct, or from P to Q and from Q to R.

When the earth is in the line of nodes of an inferior planet, the apparent motion of the former is then in a straight line, because the plane of it passes through the eye; if in a conjunction in his upper semicircle, he passes behind the sun: if in his lower semicircle, he passes before it, and will then be seen by an observer on earth to pass over the sun's disk like a round and very black spot. Were the plane of his orbit coincident with the ecliptic, this appearance would be feen exery year; but by reason of the obliquity of the two

planes to each other, it is much more rare. However, Particular he was feen in this manner November 12. 1782, at haplication 3 h. 44' in the afternoon; May 4. 1786, at 6 h. 57' lethal Phein the morning; and will be feen again December 6. nomena. 1789, at 3 h. 55' in the afternoon; but from that time not, in this island at least, until the year 1799, May 7. at 2 h. 34' in the afternoon. In like manner, Venus sometimes appears as a black spot on the fun, but much more feldom than Mercury. She was first seen by Mr Horrox, as we have already related, in the 1639; afterwards in the years 1761 and 1769; but will not afterwards be visible in this manner till the

year 1874.

When the earth is out of the line of the nodes of an inferior planet, its orbit appears an ellipfis, more or lefs eccentric according to the fituation of the eye of the spectator. Thus, suppose the earth to be as far as possible (that is, 90°) out of the line of the nodes of Mercury, the projection of his orbit will be in fuch an elliptic curve as is represented fig. 141. wherein he will appear to move in the order of the letters; direct when in his upper femicircle from a to b, from b to c, being above the fun at b in his superior conjunction; but in his inferior semicircle his motion will appear retrograde from c to d, and from d to a: in conjunction he will be at d below the fun. In these cases, the motion of Mercury is unequal: fafter near the inferior conjunction, but most unequal in the inferior semicircle, going through the unequal spaces into which the ellipsis is divided. The motions of the inferior planets, both direct and retrograde, are very unequal: and this inequality proceeds not from the eccentricity of their orbits, but from the projection of their orbits into long ellipses: and is therefore a mere optical deception.

These planets appear stationary while changing their motion from direct to retrograde, or from retrograde to direct. If the earth flood flill, the times of their appearing flationary would be at their greatest clongstion; for though it be a property of the circle that a straight line can only touch it in one point, yet when the circle is very large, the recess from the tangent is not perceptible for a confiderable time. Thus, in fig. 140. Suppose the earth to be at rest in A, Venus would appear stationary, her geocentric place continuing at T all the while the is going in her orbit from a to b; because her deviation from the visual line A'T would scarce be perceptible so near the point of con-

tact H.

To an inhabitant of the earth, therefore, the inferior planets appear always near the fun; alternately going from and returning to him, fometimes in straight. lines, at others in elliptical curves, first on one fide and then on the other; foinetimes fo near as to be rendered invisible by his stronger light. Sometimes, when in or near their nodes, they pass behind the sun in their superior semicircles, or pass between him and us; in which case they appear like black spots on his disk, as has been just now mentioned. For the better comprehending of these motions, however, we have hitherto supposed the earth to stand still in some part of its orbit, while they go round the fun in theirs: but Effects of as this is not the case, it now remains to consider the the earth's changes which take place in confequence of the earth's motion on motion. Were the earth to fland ftill in any part of the appear

her planets.

Particular its orbit as at A, the places of conjunction both in

Explication the superior and inferior semicircle, as also of the of the Cegreatest elongation; and consequently the places of dinamena, rect and retrograde motion, and of the stations of an inferior planet, would always be in the same part of the heavens. Thus, in fig. 140. upon this supposition, the place of Mercury's stations would always be the points P and R, the arc of his motion PR, and of his retrograde motion RP; whereas, on account of the earth's motion, the places where these appearances happen are continually advancing forward in the ecliptic according to the order of the figns. In fig. 142. let ABCD be the orbit of the earth; efg b that of Mercury; o the fun; GKI an arc of the ecliptic extended to the fixed flars. When the earth is at A, the fun's geocentric place is at F; and Mercury, in order to a conjunction, must be in the line AF; that 13, in his orbit he must be at f or b. Suppose him to be at f in his inferior semicircle: if the earth stood flill at A, his next conjunction would be when he is in his superior semisircle at b; the places of his greatest clongation also would be at e and g, and in the ecliptic at E and G: but supposing the earth to go on in its orbit from A to B; the fun's geocentric place is now at K; and Mercury, in order to be in conjunction, ought to be in the line BK at m. As by the motion of the earth, the places of Mercury's conjunctions with the fun are thus continually carried round in the ecliptic in confequence, so the places of his utmost elongations must be carried in consequence also. Thus, when the earth is at A, the places of his greatest elongation from the sun are in the ecliptic E and G: the motion of the earth from A to B advances them forward from G to L, and from E to I. But the geocentric motion of Mercury will best be seen in fig. 146. Here we have part of the extended ecliptic marked m, &, II, &c. in the centre of which S represents the fun, and round him are the orbits of Mercury and the earth. The orbit of Mercury is divided into 11 equal parts, fuch as he goes through once in eight days; and the divifions are marked by numeral figures, 1, 2, 3, &c. Part of the orbit of the earth is likewise divided into 22 equal arcs, each arc being as much as the earth goes through in eight days. The points of division are marked with the letters a, b, c, d, e, f, &c. and show as many several stations from whence Mercury may be viewed from the earth. Suppose then the planet to be at 1 and the earth at a; draw a line from a to 1, and it shows Mercury's geocentric place at A. In eight days he will be got to 2, and the earth to b; draw a line 2 to b, and it shows his geocentric place at B. In other eight days he will have proceeded to 3, and the earth to c; a line drawn from 3 to c will show his geocentric place at C. In this manner, going through the figure, and drawing lines from the earth at d, e, f, g, &c. through 4, 5, 6, 7, &c. we shall find his geocentric places successively at the points D, E, E, G, &c. where we may observe, that from A to and from B to C, the motion is direct; from C o D, and from D to E, retrograde. In this figure stations are marked in the earth's orbit, from hence the planet may be viewed; corresponding to ich there ought to be as many in the orbit of Mercury: and for this purpose the place of that planet is

marked at the end of every eight days for two of his Particular periodical revolutions; and to denote this, two nume-Explication

ral figures are placed at each division.

The geocentric motion of Venus may be explained homena. in a fimilar manner; only as the motion of Venus is much flower than that of Mercury, his conjunctions, oppositions, elongations, and stations, all return much more frequently than those of Venus.

To explain the stationary appearances of the planets. it must be remembered, that the diameter of the carth's orbit, and even of that of Saturn, are but mere points in comparison of the distance of the fixed stars; and therefore, any two lines, absolutely parallel, though drawn at the distance of the diameter of Saturn's orbit from each other, would, if continued to the fixed stars, appear to us to terminate in the same point. Let. then, the two circles fig. 143. represent the orbits of Venus and of the earth; let the lines AE, BF, CG, DH, be parallel to SP, we may nevertheless affirm, that if continued to the distance of the fixed stars, they would all terminate in the same point with the line SP. Suppose, then, Venus at E while the earth is at A, the vifual ray by which she is seen is the line AE. Suppofe again, that while Venus goes from E to F, the earth goes from A to B, the vifual ray by which Venus is now feen is BF parallel to AE; and therefore Venus will be all that time stationary, appearing in that point of the heaven where &P extended would terminate: this flation is at her changing from direct to retrograde. Again, Suppose, when the warth is at C, Venus is at G, and the vifual line CG; if, while the earth goes from C to D, Venus goes from G to H, fo that she is seen in the line GH parallel to CO; the will be all that time stationary, appearing in the point when a line drawn from S through P would terminate. This station is at her changing from retrograde to direct; and both are in her inferior femicircle. An inferior planet, when in conjunction with the fun Perigee in its inferior semicircle, is said to be in perigee, and and apogee in the other in apogue, on account of its different di-nots exstances from the earth. Their real distances from the plained. earth when in perigee are variable, partly owing to the eccentricities of their orbits, as well as that of the earth; and partly owing to the motions of the different bodies, by which it happens that they are in perigee in different parts of their orbits. The least possible distance is when the perigee happens when the earth is in its perihelion, and the planet in its aphelion.

The difference of distance between the earth and in-Differences ferior planets at different times, makes a confiderable in the apvariation in their apparent diameters, which indeed is parent diavery observable in all the planets; and thus they some-meters of times look very considerably larger than at others. This the planets difference in magnitude in Mercuny is nearly as 51 to 1; and in Venus, no less than 32 to 1. A common spectator, unassisted by any instrument, may observe an inferior planet alternately approach nearer and nearer the fun, until at last it comes into conjunction with him, and then to recede farther and farther till it is at its greatest elongation, which will be first on one side and then on the other: but if we observe the apparent change of place of an inferior planet in the iphere of the heavens, its direct motions, stations, and retrogradations, measuring its diameter frequently with the

micrometer-

Particular micrometer, we shall find by its decrease at some times Explication and increase at others, that its distance from us is very of the Ce-confiderably varied; fo that, taking the whole of its leftial Phenomena. course into consideration, it appears to move in a very complicated curve. See fig. 1. at C.

327 ces of the planets cxplained.

As the superior planets move in a larger orbit than Appearant the earth, they can only be in conjunction with the iun when they are on that fide opposite to the earth; as, on the other hand, they are in opposition to him when the earth is between the fun and them. They are in quadrature with him when their geocentric places are 90° diftant from that of the fun. In order to understand their apparent motions, we shall suppose them to stand still in some part of their orbit while the earth makes a complete revolution in hers; in which case, any superior planet would then have the following appearances: 1. While the earth is in her most distant semicircle, the motion of the planet will be direct. 2. While the earth is in her nearest semicircle, the planet will be retrograde. 3. While the earth is near those places of its orbit where a line drawn from the planet would be a tangent, it would appear to be stationary. Thus, in fig. 147. let. a b c d represent the orbit of the earth; S the fun; EFG an arc of the orbit of Jupiter; ABC an arc of the ecliptic projected on the sphere of the fixed stars. Suppose supiter to continue at E, while the earth goes round in her orbit according to the order of the letters a b c d. While the carth is in the femicircle most distant from Jupiter, going from it to b and from b to c, his motion in the heaven would appear direct, or from A to B and from B to C: but while the earth is in its nearest semicircle e it is the motion of Jupiter would appear retrograde from C to B and from B to A; for a, b, c, d, may be confidered as to many different flations from whence an inhabitant of the earth would view Jupiter at different Seasons of the year, and a straight line drawn from each of these stations, through F the place of Jupiter, and continued to the ecliptic, would show his apparent place there to be successively at A, B, C, B, A. While the earth is near the points of contact a and c, Jupiter would appear stationary, because the visual ray drawn through both planets does not fenfibly differ from the tangent Fa or Fc. When the earth is at b, a line drawn from b through S and F to the ecliptic, shows Jupiter to be in conjunction with the fun at B. When the earth is at d, a line drawn from d through S, continued to the ecliptic, would terminate in a point opposite to-B; which shows Jupiter then to be in opposition to the fun: and thus it appears that his motion is direct in the conjunction, but retrograde when in opposition,

> with the fun. The direct motion of a superior planet is swifter the nearer it is to a conjunction, and flower as it approaches to a quadrature with the fun. Thus, in fig. 144. let @ be the fun ; the little circle round it, the orbit of the earth, whereof a be defg is the most distant semicircle; OPQ, an arc of the orbit of Jupiter; and ABCDEFG, an arc of the ecliptic in the sphere of the fixed stars. If we suppose Jupiter to stand still at P, by the earth's motion from a to g, he would appear to move direct from A to G, describing the unequal arcs AB, BC, CD, BE, EF, FG, in equal times. When the earth is at d, Jupiter is in conjunction with the Suo at D, and there his direct motion is swiftest. When

the earth is in that part of her orbit where a line drawn Particular from Jupiter would touch it, as in the points e or g, Explication
Jupiter is nearly in quadrature with the sun; and the leftial Photography of the Control o nearer the earth is to any of those points, the flower nomena. is the geocentric motion of Jupiter; for the arcs CD. and DE are greater than BC or EF, and the arcs BC and EF are greater than AB or FG.

The retrograde motion of a superior planet is swifter the nearer it is to an opposition, and slower as it approaches to a quadrature, with the fun. Thus, let O, fig. 145, be the fun; the little circle round it the orbit of the earth, whereof g hiklm n is the nearest femicircle; OPQ, an arc of the orbit of Jupiter; NKG an arc of the ecliptic: If we suppose Jupiter to stand still at P, by the earth's motion from g to n, he would appear to move retrograde from G to N, describing the unequal arcs GH, HI, IK, KL, LM, MN, in equal times. When the earth is at &, Jupiter appears at K, in opposition to the fun, and there his retrograde motion is swiftest. When the earth is either at g or n. the points of contact of the tangents Pg and Pn, Jupiter is nearly in quadrature with the fun: and the nearer he is to either of these points, the slower is his retrogradation; for the arcs IK and KL are greater than HI or LM; and the arcs HI and LM are greater than GH or MN. Since the direct motion is swiftest when the earth is at d, and continues diminishing till it changes to retrograde, it must be insensible near the time of change: and, in like manner, the retrograde motion being swiftest when the earth is in k, and aminishing gradually till it changes to direct, must also at the time of that change be infensible; for any motion gradually decreasing till it changes into a contrary one gradually increasing, must at the time of the change be altogether infensible.

The same changes in the apparent motions of this planet will also take place if we suppose him to go on flowly in his orbit; only they will happen every year when the earth is in different parts of her orbit, and consequently at different times of the year. Thus, (fig. 147.) let us suppose, that while the earth goes round her orbit Jupiter goes from F to G, the points of the earth's orbit from which Jupiter will now appear to be flationary will be a and y: and consequently his stations must be at a time of the year different from the former. Moreover, the conjunction of Jupiter with the fun will now be when the earth is at f, and his opposition when it is at e; for which reason these also will happen at times of the year different from those of the preceding opposition and conjunction. The motion of Saturn is fo flow, that it makes but little alteration either in the times or places of his conjunction or opposition; and no doubt the same will take place in a more eminent degree in the Georgium Sidue; but the motion of Mars is fo much swifter than even that of Jupiter, that both the times and places of his conjunctions and oppositions are thereby very much altered.

Fig. 348. exemplifies the geocentric motion of Jupiter in a very intelligible manner; where o reprefents. the sun; the circle 1, 2, 3, 4, the orbit of the earth, divided into twelve equal arcs for the twelve months of the year; PQ an arc of the orbit of Jupiter, containing as much as he goes through in a year, and divided

in like manner into twelve equal parts, each as much

Particular as he goes through in a month. Now, suppose the Explication carth to be at 1 when Jupiter is at a, a line drawn of the Ce-through I and a shows Jupiter's place in the celestial pomena. ecliptic to be at A. In a month's time the earth will have moved from 1 to 2, Jupiter from a to b; and a line drawn from 2 to b will show his geocentric place to be in B. In another month, the earth will be in 3, and Jupiter at C, and consequently his geocentric place will be at C; and in like manner his place may be found for the other months at D, E, F, &c. It is likewife cafy to observe, that his geocentric motion is direct in the arcs AB, BC, ED, DE; retrograde in EF, FG, GH, HI; and direct again in IK, KL, LM, MN. The inequality of his geocentric motion is likewife apparent from the figure.

> A superior planet is in apogee when in conjunction with the fun, and in perigee when in opposition; and every one of the superior planets is at its least possible distance from the earth where it is in perigee and perihelion at the same time. Their apparent diameters are variable, according to their distances, like those of the inferior planets; and this, as might naturally be expected, is most remarkable in the planet Mars, who is nearest us. In his nearest approach, this planet is 25 times larger than when farthest off, Jupiter twice

and a half, and Saturn once and a half.

328 Of the Georgium Sidus.

330

tion of its

distance,

åç,

The honour of discovering the new attendant of the fun, called the Georgium Sidus, is undoubtedly due to Mr Heilihel; though Mr Robison, professor of Natural Philotophy in Edinburgh, has given strong reasons for supposing that it had been marked by several astronomers as a fixed flar. It was first observed by Mr Herschel on the 13th of March 1781, near the foot of Castor, and his attention was drawn by its steady light. On applying a higher magnifying power to his tele-Leope, it appeared manifeltly to increase in diameter; and two days after, he observed that its place was changed. From these circumstances he concluded, that it was a comet; and fent an account of it as such to the aftronomer-royal, which wasvery foon spread allover Europe. It was not long, however, before it was known, by the English astronomers especially, to be a planet. How difco. The circumstances which led to this discovery were, vered to be its vicinity to the ecliptic, the direction of its motion, s planet. and its being nearly stationary at the time, in such a

manner as corresponds with the like appearances of the other planets. The French astronomers, however, still imagined it to be a comet, although it had not that faint train of light which usually accompanies these bodies, nor would its fuccessive appearances correspond with fuch an hypothelis; so that they were at last obliged to own that it went round the fun in an orbit Computanearly circular. Its motion was first computed on this principle by Mr Lexel professor of astronomy at St Petersburgh; who showed, that a circular orbit, whose radius is about 19 times the distance of the earth from the fun, would agree very well with all the observations which had been made during the year 1781. On the 1st of December that year it was in opposition with the fun: whence one of its flations was certainly determined. In the mean time, however, as aftronomers were everywhere engaged in making observations on the fame star, it occurred to some, that it might possibly have been officered before, though not known to be a pla-

net. Mr Bede of Berlin, who had just published a Particular work containing all the cutalogues of zodiacal Explication which had appeared, was induced, by the observations of the Ce-which had been already made on the new place. So keltial Phowhich had been already made on the new planet, to nomena. confult these catalogues, in order to discover whether any star, marked by one astronomer and omitted by another, might not be the new planet in queilion. In the course of this inquiry, he found, that the star, Nº 964 of Mayer's catalogue, had been unobserved by others, and only once by Mr Mayer himself, so that no motion could have been perceived by him. On this Mr Bede immediately directed his telescope to that part of the heavens where he might expect to find the star marked in Mayer's catalogue, but without fuccefs. At the fame time, by the calculations already made concerning the new planet, he discovered, that its apparent place in the year 1756 ought to have been that of Mayer's flar, and this was one of the years in which he was busied in his observations; and on farther inquiry it was found, that the flar 964 had been discovered by Mr Mayer on the 15th of September 1756. So that it is now generally believed, that the flar No 964 of Mayer's catalogue was the new planet

of Herschel. Before the end of the year 1782, it was found, that the angular motion of the planet was increasing; which showed, that it was not moving in a circle, but in an eccentric orbit, and was approaching towards the fun. Astronomers, therefore, began to investigate the inequality of this angular heliocentric motival, in order to discover the form and polition of the elliphe described. This was a very difficult task, as the small inequality of motion showed that the orbit was nearly circular, and the arch already described was no more than onefiftieth part of the whole circumference. It was, however, by no means easy, from the radiation of curvature discoverable in this small street, to determine to what part of the circumference is belongs; though the professor is of opinion, that the supposition of its being the star 964 of Mayer's catalogue renders the calculation easy. On this supposition, its motion has been calculated by feveral aftronomers, as well as by Mr Robison himself. He observes, however, that if we do not admit the identity of these stars, near half a century must elapse before we can determine the elements of this planet's motion with a precision equal to that of the others.

Some astronomers are of opinion, that the new planet is the same with the star No 34 Tauri of the Britannic catalogue. "In this (fays Mr Robifon), the elements will agree very well with Flainstead's obfervation of that star on December 13. 1690, being only 40", or perhaps only 12" to the westward of it; but the latitude differs more than two minutes from Flamilead's latitude, which is properly reduced from the zenith distance. This is too great an error for him to commit in the observation; and we should therefore reject the supposition on this account alone: But there are stronger reasons for rejecting it, arising from the difagreement of those elements with the observations made on the stations of the planet in October 1781, and in March and October 1782, which give a very near aproximation of its diffance from the fun. When compared with observations of the planet near its sta-

tionary

Particular tionary points in the fpring, they give the geocentric Explication latitude confiderably too great, while they give it too

refe or retrograde morious of the inferior planets, de-To find the bits with the motion of the carth in its orbit; any of tion.

of the Ce- fmall for the fimilar observations in autumn. As the times of conjunction, utmost elongation, di-

pend on the combinations of their motions in their or-

time when their appearances will be more frequent in Mercury than rry Plant in Venus, Lecause the former moves with a swifter mowill return tion in his orbit, and confequently mul more frequentfance . ppg- ly p ifs through those places where he is in conjunction, rent time & . The time in which any of the inferior planets will return into a given fituation, may be known by the following examples: Let fig. 149, represent the orbits of Venus and the earth. Let the earth be at E, Venus at V, when the is in the inferior conjunction with the fun in m. From S, Venus and the earth would appear in conjunction in a: let Venus go round her other, and return to V; the earth taking longer time to go round than Venus, will, in the mean time, go from E, only through a part of her orbit, and Venus must overtake the earth before she can have another inferior conjunction; that is, she must, besides an entire revolution, which is equal to four right angles, go through as much more angular motion round the fun as the earth has done in the mean time, fo as to be in a right line between the fun and the earth. Suppole this is to happen when the earth is got to F, and Venus to T, the angular motions of the earth and Venus performed in the same times are reciprocally as their periodical times; and therefore as the periodical time of the earth is to the periodical time of Venus; fo is the addular motion of Venus, which is equal to four right angles, added to the angular motion of the earth, in the time between two like conjunctions of Venus, to the augular motion of the carth in the fame time: and therefore, by division of proportion, as the difference between the periodical times of Venus and Eucl. Elem the earth is to the periodical time of Venus; fo are four v. prop. 17. right angles, or 3600, to a fourth quantity; namely, to the angular motion or number of degrees which the earth goes in her orbit from the time of one conjunction of Venus to the next conjunction of the fame kind. Now the periodical time of the earth is 365 days 6 hours, or 8766 hours; the period of Venus 224 days 16 hours, or 5392 hours; the difference is 3374 hours. Say then, As 3374 hours is to 5392, fo are four right angles, or 360 degrees, to a fourth number, which is 575°; which the earth goes through in a year and 218 days. Were Venus therefore this day in an inferior conjunction with the fin, it would be a year and 218 days before the come into another conjunction of the same kind; and this alteration in time occasions a proportionable change in place; so that if one conjunction be in m, the next similar conjunction will be in mg. The time between any firmation of Mercury, with regard to the fun and the earth, and any another like fituation, may be found by the fame method. The periodical time of the earth, is 8766 hours; the period of Mercury 87 days 23 hours, or 2111 hours; the difference 6655 hours. Say then,

As 6655 is to 2111, fo are four right angles or 960°

to 114°, through which the earth passes in 116 days.

If therefore Mercury were to be this day in his infe-

Vol. II. Part II.

rior conjunction, it would be 116 days before he were Particular in a fimilar fituation.

a fimilar fituation.

This problem is commonly refolved in another man-of the Commonly refolved in a c ner. Astronomers compute the diurnal heliocentric nomena, motions of Venus and of the earth: the difference of these motions is the diurnal motion of Venus from the earth, or the quantity by which Venus would be icen to recede from the earth every day by a furtation placed in the fun: thus the mean motion of Venus re every day about 59 minutes and 8 feconds; the diffus ence is 37 minutes., Say, therefore, As 37 minutes is to 36°, or to 21,600 minutes, fo is one day to the time wherein Venus, having left the earth, recedes from her 360 degrees; that is, to the time when in the returns to the earth again, or the time between two

conjunctions of the fame kind.

The times are here computed according to the To find the mean or equable motions of the planets; and this is true times of the contherefore called a mean conjunction: but because Ve-junctions, nus and the earth are really carried in elliptic orbus, of polations, in which their motions are fometimes fwifter and fome- &c. of the times flower, the true conjunctions may happen fome planets, days either fooner or later than what these rules will give. The time of the true conjunction is to be computed from that of the mean conjunction in the following manner: Find by aftronomical tables the places of Venus and the earth in the celiptic, from which we shall have the distance of the two as seen from the sun; compute also for the same time the augular motions of these two planets for any given time, suppose fix hours; the difference of these two motions will give

it in fix hours: then fay, as this difference is to the arc between the places of Venus and the earth at the time of a mean conjunction, so is hx hours to the time between the mean conjunction and the true. This time added to or subtracted from the time of the mean conjunction, according as Venus is in antecedence or confequence from the earth, shows the time of their true conjunction.

the access of Venus to the earth, or her recess from

With regard to the conjunctions, oppositions, direct and retrograde motions, &c. of the superior planets, as they depend on the combinations of their motions with that of the earth, they will be more frequent in Saturn than in Jupiter, in Jupiter than in Mars, but most frequent of all in the Georgium Sidus; because the flower the motion of the planet is, the fooner the carth will overtake it, so as to have it again in any given fituation. Thus, suppose Saturn to be in conjunction with the fun in \(\psi\), if he were to fland full for one year, then he would again be in conjunction in m; but as he goes on flowly, according to the order of the figns, about 12° annually, the earth must go through almost 13° more than an entire revolution; so that there will be almost a year and 13 days between any conjunction between the fun and Saturn and the conjunction immediately following. As Jupiter moves in his orbit with greater velocity than Saturn, the earth must have a proportionably larger space added to the year; and as Mars moves further thill, the time betwixt any two of his conjunctions must be still longer.

The time when a superior planet will return into any given fituation, may be found by the methods al-

Particular ready laid down for the inferior planets. Thus, the Explication mean diurnal motion of the earth is about 59' 8"; of the Ce-leftial Phe- the mean motion of Saturn in a day is only two minomena, nutes: the difference 57' 8". Say therefore, As 57' 8" are to 360°, or 21,600 minutes, so is one day to the space of time wherein the earth having left Saturn, recedes from him 360°; that is, to the time of her return to Saturn again, or the time between two conjunctions, oppositions, or other like aspects. time will be found 378 days, or one year and 33 days. The mean motion of Jupiter in a day is 4' 59"; the difference between this and the earth's diurnal motion is 54' 59". Say then, as 54' 9" are to 360° or 21,600', so us one day to the space of time when the earth, having left Jupiter, will overtake him again; which will be found to be 398 days, or one year and 33 days. The mean motion of Mars is 31' 27"; the difference between which and the earth's diurnal motion is 27' 41". Say then, As 27' 41" are to 360° or 21,600', fo is one day to the space of time wherein the earth, having left Mars, recedes from him 360°; which will be found two years and 50 days. The true conjunctions, &c. may be found in the superior planets as in the inferior.

Diftance, &c. of the earth.

The earth is the next planet above Venus in the fystem. It is 95,173,000 miles from the fun; and goes round him in 365 days 5 hours 49 minutes, from any equinox or folilice to the fame again; but from any fixed flar to the fame again, as feen from the fun, in 365 days 6 hours 9 minutes; the former being the length of the tropical year, and the latter the length of the sidercal. It travels at the rate of 68,000 miles every hour; which motion, though upwards of 140 times fwifter than that of a cannon ball, is little more than half as fwift as Mercury's motion in his orbit. The earth's diameter is 7970 miles; and by turning round its axis every 24 hours from well to east, it causes an apparent diurnal motion of all the heavenly bodies from east to well. By this rapid motion of the earth on its axis, the inhabitants about the equator are carried 1042 miles every hour, whilst those on the parallel of London are carried only about 580, besides the 68,000 miles by the annual motion above-mentioned, which is common to all places whatever.

That the carth is of a globular figure may be proved from several different and evident circumstances. 1. When we are at fea on board a ship, we may be out of light of land when the land is near enough to be visible if it were not hid from our eye by the convexity of the water. Thus, let ABCD (fig. 154.) represent a portion of the globe of our earth. Let M be the top of a mountain: this cannot be feen by a person on board the ship at B, because a line drawn from M to his eye at E is intercepted by the convexity of the water; but let the ship come to C, then the mountain will be visible, because a line may be drawn from M to his eye at E. 2. The higher the eye, the farther will the view be extended. It is very common

for failors from the top of the mast of a ship to disco- Particular ver land or fhips at a much greater diffance than they Explication ver land or ships at a much greater of tance than they of the Cecan do when they stand upon deck. 3. When we less a Phestand on shore, the highest part of a ship is visible at nomena. the greatest distance. If a ship is going from us out to fea, we shall continue to fee the mast after the hull or body of the ship disappears, and the top of the mast will continue to be feen the longest. If a ship is coming towards us, the top of the mast comes first in view, and we fee more and more till at last the hull appears. If the furface of the fea were a flat plain (fig. 155.) a line might be drawn from any object fituated upon it, as the ship D, to the eye, whether placed high or low, at A or b. In this case, any object upon the earth or fea would be vilible at any distance which was not so great as to make the appearance of it too faint, or the angle under which it appears too fmall, to be feen by us. An object would be visible at the same distance, whether the eve were high or low. Not the highest, but the largest, objects would be visible to the greatest distance, so that we should be able to see the hulk of a ship farther off than the mall: All of which is contrary to experience. 4. Several navigators, fuch as Ferdinand Magellan, Sir Francis Drake, Captain Cook, have failed round the globe; not in an exact circle, the land preventing them, but by going in and out as the shores happened to lie. 5. All the appearances in the heavens are the fame, whether at land or fea. 6. Ecliples of the moon arife from the shadow of the earth, and this shadow is always circular. Although the earth prefents, during feveral hours, different portions of its furface to the moon, yet fill the shadow is round. The family inch qualities upon the furface of the earth bear no kind of proportion to its magnitude sufficient to alter the appearance of its shadow.

The earth's axis makes an angle of 232 degrees with the axis of its orbit, and keeps always the fame oblique direction, inclining nearly to the same fixed flars (A) throughout its annual course, which causes the returns of spring, summer, autumn, and winter. That the fun, and not the earth, is the centre of our Demonstrafolar fystem, may be demonstrated beyond a possibility tion of the of doubt, from confidering the forces of gravitation carth's moand projection, by which all the celelial bodies are re-tion. tained in their orbits. For, if the fun moves about the earth, the earth's attractive power must draw the fun towards it from the line of projection so as to bend its motion into a curve: But the fun being at least 227,000 times as heavy as the earth, by being fo much weightier as its quantity of matter is greater, it must move 227,000 times as slowly towards the earth as the earth does towards the fun; and confequently the earth would fall to the fun in a short time, if it had not a very firong projectile motion to carry it off. The earth, therefore, as well as every other planet in the fythem, must have a rectilineal impulse, to prevent its falling into the fun. To fay, that gravitation re-

(A) This is not strictly true, as will appear when we come to treat of the recession of the equinoctual points in the heavens, which recession is equal to the deviation of the earth's axis from its parallelism: but this is rather too small to be sensible in an age, except to those who make very nice observations.

Particular tains all the other planets in their orbits without af-Explication feeting the earth, which is placed between the orbits of Mars and Venus, is as abfund as to suppose that fix nomena. cannon bullets might be projected upwards to different heights in the air, and that five of them should fall down to the ground; but the fixth, which is nerther the highest nor the lowest, should remain suspended in the air without falling, and the earth move round about it.

> There is no fuch thing in nature as a heavy body moving round a light one as its centre of motion. A pebble faltened to a mill-flone by a flring, may by an eafy impulse be made to circulate round the mill-flone; but no impulse can make a mill-stone circulate round a loofe pubble; for the mill-flone will go off, and carry the pebble along with it.

> The fun is so immensely bigger and heavier than the earth, that, if he was moved out of his place, not only the earth, but all the other planets, if they were united into one mafs, would be carried along with the fun as

the pubble would be with the mill-flone.

335 acc.

By confidering the law of gravitation, which takes proportion place throughout the folar fystem, in another light, it al decrease will be evident that the earth moves round the fun in a of gravity, year, and not the fun round the earth. It has been observed, that the power of gravity decreases as the square of the distance increases; and from this it follows with mathematical certainty, that when two or more bodies move round another as their centre of motion, the fquares of their periodic times will be to one another in the same proportion as the cubes of their distances from the central body. This holds precifely with regard to the planets round the fun, and the fatellige round the planets; the relative distances of all which are well known. But, if we suppose the sun to move round the earth, and compare its period with the moon's by the above rule, it will be sound that the fun would take no less than 173,510 days to move round the earth; in which case our year would be 475 times as long as it now is. To this we may add, that the aspects of increase and decrease of the planets, the times of their feeming to fland fill, and to move direct and retrograde, answer precisely to the earth's motion; but not et all to the fun's without introducing the most abfurd and monftrous suppositions, which would destroy all harmony, order, and fimplicity, in the fyttem. Moreover, if the earth be supposed to stand still, and the flars to revolve in free spaces about the earth in 24 hours, it is certain that the forces by which the stars revolve in their orbits are not directed to the earth, but to the centres of the feveral orbits; that is, of the feveral parallel circles which the flars on different fides of the equator describe every day; and the like inferences may be drawn from the supposed diurnal motion of the planets, fince they are never in the equinoctial but twice in their courfes with regard to the flarry heavens. But, that forces should be directed to no central body, on which they physically depend, but to innumerable imaginary points in the axis of the earth produced to the poles of the heavens, is an hypothesis too absurd to be allowed of by any rational creature. And it is still more absurd to imagine that these forces should increase exactly in proportion to the distances from this axis; for this is ar indication of an increase to infinity; whereas the force of attraction is found to decrease in receding from the fountain P. from whence it flows. But the faither any flur is from Explicate. the quiefcent pole, the greater must be the orbit which that the it describes; and yet it appears to go round in the same noncera. time as the nearest star to the pole does. And if we take into confideration the twofold motion observed in the flars, one diurnal round the axis of the earth in 24 hours, and the other round the axis of the ecliptic in 25,920 years, it would require an explication of fuch a perplexed composition of forces, as could by no means be reconciled with any physical theory.

The strongest objection that can be made against Objection the earth's motion round the fun is, that in opposite against the points of the earth's orbit, its axis, which always keeps with's a parallel direction, would point to different fixed flare; answered. which is not found to be fact. But this objection is eafily removed, by confidering the immense distance of the flars in respect of the diameter of the earth's orbit; the latter being no more than a point when compared to the former. If we lay a ruler on the fide of a table, and along the edge of the ruler view the top of a spire at ten miles diffance; then lay the ruler on the opposite fide of the table in a parallel fituation to what it had before, and the spire will still appear along the edge of the ruler; because our eyes, even when ashited by the best instruments, are incapable of distinguishing to small

a change at fo great a distance. Dr Bradley, our late astronomer-royal, found by a Earth's long feries of the most accurate observations that there motion deis a small apparent motion of the fixed flars, occasioned monftrated by the aberration of their light; and fo exactly an aberration fwering to an annual motion of the earth, as evinces of light. the fame, even to a mathematical demonstration. He confidered this matter in the following manner: he imagined CA, fig. 33. to be a ray of light falling perpendicularly upon the line BD; that, if the eye is at rest at A, the object must appear in the direction AC,

is propagated in time, with a velocity that is to the velocity of the eye as CA to BA; then light moving from C to A, whilft the eye moves from B to A, that particle of it by which the object will be discerned when the eye comes to A, is at C when the eye is at Joining the points BC, he supposed the line CB to be a tube, inclined to the line BD in the angle DBC, of fuch diameter as to admit but one particle of light. Then it was easy to conceive, that the particle of light at C, by which the object must be seen. when the eye, as it moves along, arrives at A, would pass through the tube BC, if it is inclined to BD in the angle DBC, and accompanies the eye in its motion from B to A; and that it could not come to the eye placed behind fuch a tube, if it had any other inclination to the line BD. If, instead of supposing CB fo finall a tube, we imagine it to be the axis of a larger; then, for the fame reason, the particle of light at

C would not pass through the axis, unless it is inclined to BD in the angle CBD. In like manner, if the eye

moved the contrary way, from D towards A, with

the fame velocity, then the tube must be inclined in the angle BCD. Although, therefore, the true or real

place of an object is perpendicular to the line in which the eye is moving, yet the vifible place will not be fo;

whether light be propagated in time or in an inflant.

But if the eye is moving from B towards A, and light

fince that, no doubt, must be in the direction of the 3 T 2 tube;

Particular tube; but the difference between the true and appa-Explication rent place will be cateris paribus, greater or lefs, acof the Ce- cording to the different proportion between the velonomena. city of light and that of the eye. So that, if we could fuppose that light was propagated in an instant, then there would be no difference between the real and vifible place of an object, although the eye was in motion; for in that case, AC being infinite with respect to AB, the angle ACB, the difference between the true and visible place, vanishes. But if light be propagated in time, it is evident, from the foregoing confiderations, that there will be always a difference between the real and visible place of an object, unless the eye is moving either directly towards or from the object. And in all cases the sine of the disference between the real and visible place of the object will be to the fine of the visible inclination of the object to the line in which the eye is moving, as the velocity of the eye is to the velocity of light.

> He then shows, that if the earth revolve round the fun annually, and the velocity of light be to the velocity of the earth's motion in its orbit, as 1000 to 1, that a flar really placed in the very pole of the ecliptic would, to an eye carried along with the earth, feem to change its place continually; and, neglecting the finall difference on the account of the earth's diurnal revolution on its axis, would feem to deferibe a circle round that pole every way diffant from it 31; fo that its longitude would be varied through all the points of the ecliptic every year, but its latitude would always remain the fame. Its right afcention would also change, and its declination, according to the different fituation of the fun with respect to the equinoctial points, and its apparent diffance from the north pole of the equator, would be 71 less at the autumnal than at the vernal

equinox.

338 Velocity of light.

By calculating exactly the quantity of aberration of the fixed flars from their place, he found that light came from the fun to us in 8' 13"; fo that its velocity is to the velocity of the earth in its orbit as 10,201

Errors in the obferwation of fmall angles.

carth's

motion

It must here be taken notice of, however, that Mr Nevil Maskelyne, in attempting to find the parallax of Sirius, with a ten-fect fector, observed, that by the friction of the plummet line on the pin which fulpended it, an error of 10', 20', and fometimes 30', was committed. The pin was $\frac{1}{3}$ of an inch diameter; and though he reduced it to $\frac{1}{3}$ of an inch, the error still amounted to 3". All observations, therefore, that have hitherto been made in order to discover the parallax of the fixed stars are to be difregarded.

It is also objected, that the sun seems to change his place daily, so as to make a tour round the starry heaagainst the vens in a year. But whether the fun or earth moves, this appearance will be the fame; for when the earth is in any part of the heavens, the fun will appear in auswered. the opposite. And therefore this appearance can be no objection against the motion of the earth.

It is well known to every person who has failed on fmooth water, or been carried by a fiream in a calm, that, however fast the vessel goes, he does not feel its progressive motion. The motion of the earth is in- Particular comparably more fmooth and uniform than that of a Explication fhip, or any machine made and moved by human art leftial Pheand therefore it is not to be imagined that we can feel nomens.

We find that the fun, and those planets on which there are vilible spots, turn round their axes: for the fpots move regularly over their difks (B). From house we may reafonably conclude, that the other planets on which we see no spots, and the earth, which is likewise a planet, have such rotations. But being incapable of leaving the earth, and viewing it at a diffance, and its rotation being fmooth and uniform, we can neither fee it move on its axis as we do the planets, nor feel ourfelves affected by its motion. Yet there is one effect of Argument fuch a motion, which will enable us to judge with cer- for the tainty whether the earth revolves on its axis or not ton from All globes which do not turn round their axes will be us toheroi. perfect fpheres, on account of the equality of the weight dal figure. of bodies on their furfaces; especially of the fluid part .. But all globes which turn on their axes will be oblite fpheroids; that is, their furfaces will be higher or farther from the centre in the equatorial than in the polar regions: for as the equatorial parts move quickelt, they will recede farthest from the axis of motion, and enlarge the equatorial diameter. That our earth is really of this figure, is demonstrable from the anequal vibrations of a pendulum, and the unequal lengths of degrees in different latitudes. Since then the earth is higher at the equator than at the poles, the few, which naturally runs downward, or toward the places which are nearest the centre, would run towards the polar regions, and leave the equatorial parts dry, if the centrifugal force of these parts, by which the waters were carried thither, did not keep them from returning. The earth's equatorial diameter is 36 miles longer than

Bodies near the poles are heavier than those towards Weight of the equator, because they are nearer the earth's centre, bodies where the whole force of the earth's attraction is accu-increases mulated. They are also heavier, because their centri-poles. fugal force' is lefs, on account of their diurnal motion being flower. For both these reasons, bodies carried from the poles towards the equator gradually lofe their weight. Experiments prove, that a pendulum which vibrates seconds near the poles vibrates slower near the equator, which shows that it is lighter or less attracted there. To make it oscillate in the same time, it is found necessary to diminish its length. By comparing the different lengths of pendulums swinging seconds at the equator and at London, it is found that a pendulum must be 2 160 lines shorter at the equator than at the poles. A line is a twelfth part of

an inch.

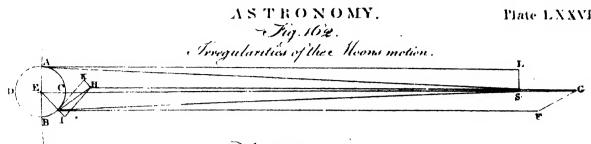

If the earth turned round its axis in 84 minutes 43 feconds, the centrifugal force would be equal to the power of gravity at the equator; and all bodies there would entirely lofe their weight. If the earth revolved quicker, they would all fly off and leave it.

A person on the earth can no more be sensible of its undisturbed motion on its axis, than one in the cabin

ο£

(n) This, however, must be understood with some degree of limitation, as will evidently appear from what has been already faid concerning the variable motion both of the spots of the sun and planets.

ABalle Win Mirl Soulple of find .

Particular of a ship on smooth water can be fensible of the ship's Explication motion, when it turns gently and uniformly round. Ιt of the Ce- is therefore no argument against the earth's diurnal lesti i Phenomera. motion, that we do not feel it; nor is the apparent revolutions of the celestial bodies every day a proof of the reality of these motions: for whether we or they revolve, the appearance is the very fame. A person looking through the cabo windows of a ship, as firongly fancies the objects on land to go round when

Partla mo-

the fup turns as if they were actually in motion. If we could translate ourfalves from planet to planet, we should full find that the stars would appear of the ccheficl ap- fance magnitudes, and at the fame diffances from each pearances other, as they do to us here; because the width of the from differ-remotelt planet's orbit bears no fensible proportion to ent planets the deliance of the flars. But then the heavens would from to revolve about very different axes; and confequently, those quiescent points, which are our poles in the heavens, would feem to revolve about other points, which, though apparently in motion as fren from the eart's, would be at reft as feen from any other planet. Thus the axis of Venus, which lies at right angles to the axis of the earth, would have its motionless poles in two opposite points of the heavens lying almost in our equinochial, where the motion appears quickest, because it is securingly performed in the greatest circle: and the very poles, which are at rest to us, have the quickest motion of all as seen from Venus. To Mars and Japaner the heavens appear to turn round with very different mission on the same axis, whose poles are about 2.1 degrees from ours. Were we on Jupiter, and should be at first amazed at the rapid motion of the heaven; the fun and flars going round in 9 hours to months. Could we go from thence to Venus, we hand the account to printed at the flowners of the heaven's account the fun going but once round in 584 hours, and the large as 540. And could we go from Venue to the moon, we should see the heavens turn round with a yet flower motion; the fun in 708 hours, the stars in 655. As it is impossible these various circumvolutions in luch different times, and on such different axes, can be real, so it is unreasonable to suppose the beavens to revolve about our earth more than it does about any other planet. When we reflect on the vast distance of the fixed stars, to which 190,000,000 of miles, the diameter of the earth's orbit, is but a point, we are filled with amazement at the immenfity of their distance. But if we try to frame an idea of the extreme rapidity with which the flars must move, if they move round the earth in 24 hours, the thought becomes fo much too big for our imagination, that we can no more conceive it than we do infinity or eternity. If the fun was to go round the earth is 24 hours, he must travel upwards of 300,000 miles in a minute : but the stars being at least 400,000 times as far from the fun as the fun is from us, those about the equator must move 400,000 times as quick. And all this is to ferve no other purpose than what can be as fully and much more simply obtained by the earth's turning round castward, as on an axis, every 24 hours, causing thereby an apparent diurnal motion of the fun weftward, and bringing. about the alternate returns of day and night.

As to the common objections against the carth's motion on its axis, they are all easily answered and set aside. That it may turn without being seen or felt

by us to do fo, has been already shown. But some Particular are apt to imagine, that if the earth turns eastward (as Explication it certainly does if it turns at all), a ball fired perpen-leftial Phendicularly upwards in the air must fall considerably west-nomena. ward of the place it was projected from. The objection, which at first feems to have some weight, will be found to have none at all, when we consider that the gun and ball partake of the earth's motion; and therefore the ball being carried forward with the air as quick as the earth and air turn, must fall down on the fame place. A stone let fall from the top of a mainmall, if it meets with no obliacle, falls on the deck as near the foot of the mast when the ship sails as when it does not. If an inverted bottle full of liquor be hung up to the ceiling of the cabin, and a finall hole be made in the cork, to let the liquor drop through on the floor, the drops will fall juit as far forward on the floor when the ship fails as when it is at rest. And gnats or flies can as eafily dance among one another in a moving cabin as in a fixed chamber. As for those Scripture expressions which seem to contradict the carrit's motion, this general answer may be made to them all, viz. It is plain from many inflances, that the Scriptures were never intended to instruct us in philosophy or altronomy; and therefore on those subjects expressions are not always to be taken in the literal fense, but for the most part as accommodated to the common apprehensions of mankind. Men of fense in all ages, when not treating of the sciences purposely, have followed this method; and it would be in vain to follow any other in addressing ourselves to the vulgar, or bulk of any community.

The following experiment will give a plain idea of 3 urnal the diurnal or annual motions of the earth, together motion of with the different lengths of days and nights, and all the earth, the beautiful variety of the feafons, depending on those rent chan-

Take about seven feet of strong wire, and bend it seasons ilinto a circular form, as a b c d, which being viewed ob-luftrated liquely, appears elliptical, as in the figure. Place a by experilighted candle on a table; and having fixed one end of Fig. 172 a filk thread K to the north pole of a small terrestrial globe H, about three inches diameter, cause another person to hold the wire circle, so that it may be parallel to the table, and as high as the flame of the candle I, which should be in or near the centre. Then having twifted the thread as towards the left hand, that by untwifting it may turn the globe round eaftward, or contrary to the way that the hands of a watch move, hang the globe by the thread within this circle, almost contiguous to it; and as the thread untwists, the globe (which is enlightened half round by the candle as the earth is by the fun will turn round its axis, and the different places upon it will be carried through the light and dark hemispheres, and have the appearance of a regular succession of days and nights, as our earth has in reality by fuch a motion. As the globe turns, move your hand flowly, fo as to carry the globe round the candle according to the order of the letters a he die keeping its centre even with the wire circle; and you will perceive, that the candle, being ftill perpendicul to the eduator, will enlighten the globe from po pole in its whole motion round the circle; and every place on the globe goes equally through light and the dark, as it turns round by the untwill-

344 Another phjection infwered.

Particular ing of the thread, and therefore has a perpetual equi-Explication nox. The globe thus turning round, represents the of the Ce- earth turning round its axis; and the motion of the nomena. globe round the candle represents the earth's annual motion round the fun; and shows, that if the earth's orbit had no inclination to its axis, all the days and nights of the year would be equally long, and there would be no different seasons. Hence also it appears why the planets Mars and Jupiter have a perpetual equinox, namely, because their axis is perpendicular to the plane of their orbit, as the thread round which the globe turns in this experiment is perpendicular to the plane of the area enclosed by the wire. - But now defire the person who holds the wire to hold it obliquely in the polition ABCD railing the lide as just as much as he depresses the side 19, that the slame may be still in the plane of the circle; and twisting the thread as before, that the globe may turn round its axis the same way as you carry it round the candle, that is, from well to east; let the globe down into the lowermost part of the wire circle at 14: and if the circle be properly inclined, the candle will shine perpendicularly on the tropic of Cancer; and the frigid zone, lying within the arctic or north polar circle, will be all in the light, as in the figure; and will keep in the light, let the globe turn round its axis ever fo often. From the equator to the north polar circle, all the places have longer days and fliorter nights; but from the equator to the fouth polar circle, just the reverse. The fun does not let to any part of the north frigid zone, as shown by the candle's shining on it, so that the motion of the globe can carry no place of that zone into the dark; and at the fame time the fouth frigid zone is involved in darkness, and the turning of the globe brings none of its places into the light. If the earth were to continue in the like part of its orbit, the fun would never fet to the inhabitants of the north frigid zone, nor rife to those of the fouth. At the equator it would be always equal day and night; and as places are gradually more and more distant from the equator towards the arctic encle, they would have longer days and shorter nights; whilst those on the fouth side of the equator would have their nights longer than their days. In this case, there would be continual summer on the north fide of the equator, and continual winter on the fouth fide of it.

But as the globe turns round its axis, move your hand flowly forward, so as to carry the globe from H towards E, and the boundary of light and darkness will approach towards the north pole, and recede towards the fouth pole; the northern places will go through less and less of the light, and the fouthern places through more and more of it; showing how the norther days decrease in length and the southern days in the length and the southern days in the length and the southern days in the length are the length at E, it is at a mean state between the length and highest parts of its orbit; the candle is directly over the equator, the boundary of light and darkness just reaches to both the poles, and all places on the globe go equally through the light and dark hemispheres, showing that the days and nights are then at all places of the earth, the poles only except-for the fun is then fetting to the north pole and to the fouth pole.

Continue moving the globe forward, and as it goes

through the quuter A, the north pole recedes still far- Particular ther into the dark hemisphere, and the south pole ad Expleation vances more into the light, as the globe comes nearer leftial Photo go; and when it comes there at F, the candle is nomena. directly over the tropic of Capricoin; the days are at . the fhostell and nights at the longell, in the northern hemitphere, all the way from the equator to the arche circle; and the reverle in the fouthern hemisphere from the equator to the antarctic circle; within which circles it is dark to the north frigid zone, and light to

Continue both motions; and as the globe moves through the quarter B, the north pole advances towards the light, and the fouth pole recedes towards the dark; the days lengthen in the northern hemisphere and shorten in the southern; and when the globe comes to G, the candle will be again over the equator (as when the globe was at E), and the days and nights will again be equal as formerly; and the north pole will be just coming into the light, the fouth pole going out

Thus we see the reason why the days lengthen and shorten from the equator to the polar circles every year; why there is fometimes no day or night for many turnings of the earth, within the polar circles; why there is but one day and one night in the whole year at the poles; and why the days and nights are equally long all the year round at the equator, which is always equally cut by the circle sounding is at and darkness.

The inclination of an axis or orbit is more relative, because we compare it with some other axis or insit which we consider as not inclined at all.

Which we consider as not inclined at all.

We are upon, we consider it as having so an incline and yet, if we travel 90 degrees from the fact of the formers shall then have an horizon perpendicular to the formers.

but it was fill be level to us.

Let us now take a view of the earth in its annual Different course round the sun, considering its orbit as maring no seasons per inclination; and its axis as inclining 234 degrees from ticularly a line perpendicular to the plane of its orbit, and keep-explained. ing the same oblique direction in all parts of its annual course; or, as commonly termed, keeping always parallel to itself.

Let a, b, c, d, e, f, g, h, be the earth in eight diffe- Fig. 174. rent parts of its orbit, equidifiant from one another; Ns its axis, N its north pole, s its fouth pole, and S the fun nearly in the centre of the earth's orbit. As the earth goes round the fun according to the order of the letters abed, &c. its axis No keeps the same obliquity, and is still parallel to the line MNs. When the earth is at a, its north pole inclines towards the fun S, and brings all the northern places more into the light, than at any other time of the year. But when the earth is at e in the opposite time of the year, the north pole declines from the fun, which occasions the northern places to be more in the dark than in the light, and the reverse at the southern places; as is evident by the figure which is taken from Dr Long's astronomy. When the earth is either at c or g, its axis inclines not either to or from the fun, but lies sidewife to him, and then the poles are in the boundary of light and darkness; and the sun, being directly over the equator, makes equal day and night at all places.

Fig. 177.

Particular When the earth is at b, it is half way between the fumexplication mer folftice and harvest equinox; when it is at d, it is of the Ce- half way from the harvest equinox to the winter solchial Phenomena. Rice; at f, half way from the winter folitice to the fpring equinox; and at b, half way from the fpring

equinox to the fummer folflice.

From this oblique view of the earth's orbit, let us fuppole ourselves to be raised far above it, and placed just over its centre S, looking down upon it from its north pole; and as the earth's orbit differs but very little from a circle, we shall have its figure in such a vicw represented by the circle ABCDEFG. Let us suppose this circle to be divided into 12 equal parts, called figns, having their names affixed to them; and each fign into 30 equal parts, called degrees, numbered 10, 20, 30, as in the uttermost circle of the figure, which represents the great ecliptic in the heavens. The earth is shown in eight different positions in this circle; and in each polition Æ is the equator, T the tropic of Cancer, the dotted circle the parallel of London, U the arctic or north polar circle, and P the north pole, where all the meridians or hour circles meet. As the earth goes round the fun, the north pole keeps constantly towards one part of the heavens, as it keeps in the figure towards the right hand fide of the plate. When the earth is at the beginning of Libra, name-

When the earth is at the beginning of Libra, namely on the 1th of blanch, in this figure the fun S as feen from the earth, appears at the beginning of Aries in the property of the light, and the fun is vertical to the country which, together with the tropic of Cancer, smalled off London, and arctic circle, are all control of the circle bounding light and darkness, committee with the fix o'clock hour circle, and therefore, are the first and nights are equally long at all places: for the part of the meridian ETLa comes into the light at lix in the morning, and, revolving with the light at lix in the morning, and, revolving with the earth according to the order of the hour letters, goes Into the dark at fix in the evening. There are 24 meridians or hour circles drawn on the earth in this figure, to show the time of funrising and fetting at

different feasons of the year.

As the earth moves in the ecliptic according to the order of the letters ABCD, &c. through the figns Libra, Scorpio, and Sagittarius, the north pole P comes more and more into the light; the days increase as the nights decrease in length, at all places north of the equator Æ; which is plain by viewing the earth at bon the 5th of May, when it is in the 15th degree of Scorpio, and the fun as feen from the earth appears in the 15th degree of Taurus. For then the tropic of Cancer T is in the light from a little after five in the morning till almost seven in the evening; the parallel of London, from half an hour past four till half an hour past seven; the polar circle U, from three till nine; and a large track round the north pole P has day all the 24 hours, for many rotations of the earth on its

When the earth comes to c (fig. 174.) at the beginning of Capricorn, and the fun as feen from the earth appears at the beginning of Cancer, on the 21st of June, as in this figure, it is in the position C in fig. 177; and its north pole inclines towards the fun, fo as to bring all the north frigid zone into the light, and the northern

parallels of latitude more into the light than the dark Particularfrom the equator to the polar circle: and the more fo Explication as they are farther from the equator. The tropic of Can-of the Cecer is in the light from five in the morning till feven at nomena. night, the parallel of London from a quarter before. four till a quarter after eight; and the polar circle just. touches the dark, so that the sun has only the lower half of his disk hid from the inhabitants on that circle for a few minutes about midnight, supposing no incqualities in the horizon, and no refractions.

A bare view of the figure is enough to show, that as the earth advances from Capricorn towards Aries, and the fun appears to move from Cancer towards Libra, the north pole recedes from the light, which causes the days to decrease and the nights to increase in length, till the earth comes to the beginning of Aries, and then they are equal as before; for the boundary of light and darkness cuts the equator and all its parallels equally, or in halves. The north pole then goes into the dark, and continues therein until the earth goes half way round its orbit; or, from the 23d or September till the 20th of March. In the middle between these times, viz. on the 22d of December, the north pole is as far as it can be in the dark, which is 23 th degrees equal to the inclinations of the earth's axis from a perpendicular to its orbit: and then the northern parallels are as much in the dark as they were in the light on the 21st of June; the winter nights being as long. as the fummer days, and the winter days as short as the fummer nights. Here it must be noted, that of all that has been faid of the northern hemisphere, the contrary must be understood of the southern; for on different fides of the equator the feafons are contrary, because, when the northern hemisphere inclines towards the fun, the fouthern declines from him.

stantly keeping in its lower focus, which is 1,617,941 fun appear miles from the middle point of the longer axis, the earth bigger in comes twice fo much, or 3,235,882 miles nearer the fun winter than at one time of the year than at another; for the fun appearing under a larger angle in our winter than fummer, proves that the earth is nearer the fun in winter. But here this natural question will arise, Why have we not the hottest weather when the earth is nearest the fun? In answer it must be observed, that the eccentricity of the earth's orbit, or 1,617,941 miles, bears no greater proportion to the earth's mean distance from the fun than 17 does to 1000; and therefore this fmall difference of distance cannot occasion any great. difference of heat or cold. But the principal cause of this difference is, that in winter the sun's rays fall so obliquely upon us, that any given number of them is spread over a much greater portion of the earth's surface where we live; and therefore each point must then have fewer rays than in fummer. Moreover, there comes a greater degree of cold in the long winter nights than there can return of heat in fo short days; and on both these accounts the cold must increase. But in fummer the fun's rays fall more perpendicularly upon. us: and therefore come with greater force, and in greater numbers, on the same place; and by their long continuance, a much greater degree of heat is imparted by day than can fly off by night. Besides, those parts which are once heated, retain the heat for some

time; which, with the additional heat daily imparted,

The earth's orbit being elliptical, and the fun con-why the

Particular makes it continue to increase, though the fun declines Explication towards the fouth: and this is the reason why July is of the Ce-hotter than June, although the fun has withdrawn nomena, from the summer tropic; as we find it is generally hotter at three in the afternoon, when the fun has gone towards the west, than at noon when he is on the meridian. Likewise those places which are well cooled require time to be heated again; for the fun's rays do not heat even the furface of any body till they have been some time upon it. And therefore we find January for the most part colder than December, alsho' the fun has withdrawn from the winter tropic, and begins' to dert his beams more perpendicularly upon us. An iron bar is not heated immediately upon being in the fire, nor grows cold till fome time after it has been taken out.

It has been already observed, that by the earth's motion on its axis, there is more matter accumulated all around the equatorial parts than anywhere else on the earth.

The fun and moon, by attracting this redundancy of matter, bring the equator fooner under them in every return towards it, than if there was no fuch accumulation. Therefore, if the fun fets out, as from any ftar, or other fixed point in the heavens, the moment when he is departing from the equinoctial or from either tropic, he will come to the fame equinox or tropic again 20 min. 17% fec. of time, or 50 feconds of a degree, before he completes his course, so as to arrive at the same fixed star or point from whence he set out. For the equinoctial points recede 50 seconds of a degree westward every year, contrary to the fun's annual progressive motion.

When the fun arrives at the same equinocial or solflitial point, he finishes what we call the Tropical Year; which, by observation, is found to contain 365 days 5 hours 48 minutes 57 feconds: and when he arrives at the fame fixed ftar ngain, as feen from the earth, he completes the fidereal year, which contains 365 days 6 hours 9 minutes 141 feconds. The fidereal year is therefore 20 minutes 17 1 feconds longer than the folar or tropical year, and o minutes 141 feconds longer than the Julian or the civil year, which we state at g65 days 6 hours, fo that the civil year is almost a mean

between the sidereal and tropical.

As the sun describes the whole ecliptic, or 360 degrees, in a tropical year, he moves 59' 8" of a degree every day at a mean rate; and consequently 50" of a degree in 20 minutes 171 feconds of time: therefore he will arrive at the fame equinox or foldice when he is 50" of a degree short of the same star or fixed point in the heavens from which he fet out the year before. So that, with respect to the fixed stars, the sun and equinoctial points fall back (as it were) 30 degrees in 2160 years, which will make the stars appear to have gone 30 deg. forward with respect to the figns of the ecliptic in that time: for the same signs always keep in the same points of the ecliptic, without regard to the constellations.

To explain this by a figure, let the fun be in conof H. at any given time. Then, making of 8, at any given time. Then, making evolutions through the ecliptic VWX, at the nany fidereal years, he will be found again

but at the end of fo many Julian years, he

will be found at M, short of S: and at the end of so Particular many tropical years he will be found short of M, in the Explication 30th degree of Taurus at T, which has receded back of the Ce-from S to T in that time, by the precession of the nomena. equinoctial points of Aries and a Libra. The are . ST will be equal to the amount of the precession of the equinox in 2160 years, at the rate of 50" of a degree, or 20 minutes 17 feconds of time annually; this, in fo many years, makes 30 days 10; hours, which is the difference between 2160 fidereal and tropicalyears; and the arc MT will be equal to the space moved through by the fun in 2160 times 11 min. 8 fec. or 16 days 13 hours 48 minutes, which is the difference between 1260 Julian and tropical years.

The anticipation of the equinoxes, and confequent-Anticipaly of the feafons, is by no means owing to the precess tion of the fion of the equinoctial and folditial points in the equinoxes heavens (which can only affect the apparent motions, explained. places, and declinations, of the fixed stars), but to the difference between the civil and folar year, which is 11 minutes 3 feconds; the civil year containing 365 days 6 hours, and the solar year 365 days 5 hours 48 mi- 4

nutes 57 seconds.

The above 11 minutes 3 feconds, by which the civil or Julian year exceeds the folar, amounts to 11 days in 1433 years; and so much our seasons have fallen back with respect to the days of the mosths, fines the time of the Nicene council in A. D. 3334 and therefore, in order to bring back all the fasts and restricted to the days then fettled, it was requilite to suppress is nominal days: and, that the fame (calons might be kept to the fame times of the year for the future, to leave out the biffextile day in February at the end of every contary of years not divisible by 4; reckening them only pon-mon years, as the 17th, 18th, and 19th centuries, it. the years 1700, 1800, 1900, &c. because a say intercalated every fourth year was too much ; and retaining the biffextile day at the end of those centuries of years which are divilible by 4, as the 16th, 20th, and 24th centuries, viz. the years 1600, 2000, 2400, &c. otherwife, in length of time, the feafons would be quite reverled with regard to the months of the year; though it would have required near 23,783 years to have brought about such a total change. If the carth had made exactly 365 diurnal rotations on its axis, whilst it revolved from any equinoctial or folfitial point to the fame again, the civil or folar years would always have kept pace together, and the flyle would never have needed any alteration.

Having thus mentioned the cause of the precession of the equinoctial points in the heavens, which occasions a flow deviation of the earth's axis from its parallelisin, and thereby a change of the declination of the flars from the equator, together with a flow apparent motion of the stars forward with respect to the signs of the ecliptic, we shall now explain the phenomena by a diagram.

Let NZSVL be the earth, SONA its axis produ- Fig. 182. ced to the starry heavens, and terminating in A, the present north pole of the heavens, which is vertical to N the north pole of the earth. Let EOQ be the equator, Too Z the tropic of Cancer, and VTve the trepic of Capricorn; VOZ the ecliptic, and BO ite axis, both which are immoveable among the stars. But as the equinoctial points recede in the ecliptic, the earth's

Mained. Fig. 181.

Precession

Particular axis SON is in motion upon the earth's centre O, in Explication such a manner as to describe the double cone NOn and of the Ce-SOs, round the axis of the ecliptic BO, in the time nomena. that the equinoctial points move quite round the ecliptic, which is 25.920 years; and in that length of time, the north pole of the earth's axis produced, describes the circle ABCDA in the flarry heavens, round the pole of the ecliptic, which keeps immoveable in the centre of that circle. The earth's axis being 232 degrees inclined to the axis of the ecliptic, the circle ABCDA described by the north pole of the earth's axis produced to A, is 47 degrees in diameter, or double the inclination of the earth's axis. In confequence of this, the point A, which at present is the north pole of the heavens, and near to a flar of the fecond magnitude in the tail of the constellation called the Little Bear. must be deserted by the earth's axis; which moving backwards a degree every 72 years, will be directed towards the star or point B in 6480 years hence; and in double of that time, or in 12,960 years, it will be directed towards the flar or point C, which will then be the north pole of the heavens, although it is at prefent 81 degrees fouth of the zenith of London L. The prefent polition of the equator EOQ will then be changed into aOq, the propic of Cancer Taz Z into Vizz, and the troph of Capricon VI by into 140 Z; as is evident by the figure. And the fun, in the fame part of the heavens where he is now over the earthly tropic of Capricons, and makes the thortest days and longest nights in the northest hemisphere, will then be over the earthly tropic of Lauret, and make the days longest and mights house. So that it will require 12,960 years yer more, or ar pace N quite round, so as to be directed to mand that posts of the heavens which is vertical to And then, and not till then, the same point moin, &c. by the earth's diarnal motion, will describe them over again.

" From the shifting of the equinoctial points, and with them all the figns of the ecliptic, it follows, that those fars, which in the infancy of aftronomy were in Aries are now got into Taurus; those of Taurus into Gemini, &c. Hence likewise it is that the stars which rose or let at any particular season of the year, in the times of Hesiod, Eudoxus, Virgil, Pliny, &c. by no means

answer at this time to their descriptions.

The moon is not a planet, but only a satellite, or attendant of the earth, going round the earth from change to change in 29 days 12 hours and 44 minutes, and round the fun with it every year. The moon's diameter is 2180 miles; and her distance from the earth's centre is 240,000. She goes round her orbit in 27 days 7 hours 43 minutes, moving about 2290 miles every hour; and turns round her axis exactly in the time that she goes round the earth, which is the reason of her keeping always the same side towards us, and that her day and night taken together is as long as our lunar

The moon is an opaque globe like the earth, and shines only by reslecting the light of the sun: therefore, whilft that half of her which is towards the fun is enlightened, the other half must be dark and invisible. Hence she disappears when she comes between us and the Sun; because her dark side is then towards us. When

Vol. II. Part II.

the is gone a little way forward, we fee a little of her Particular enlightened fide; which still increases to our view as the Explication advances forward, until the comes to be opposite to the of the Coffee fun; and then her whole enlightened side is towards lessed Party fun; and then her whole enlightened fide is towards homens the earth, and she appears with a round illuminated orb, which we call the full moon; her dark fide being then turned away from the earth. From the full she feems to decrease gradually as the goes through the other half of her course; showing us less and less of her enlightened fide every day, till her next change or conjunction with the fun, and then she disappears as before.

The moon has scarce any difference of seasons; her axis being almost perpendicular to the ecliptic. What is very fingular, one half of her has no darkness at all; the earth constantly affording it a strong light in the fun's ablence; while the other half has a fortnight's

darkness and a fortnight's light by turns.

Our earth is thought to be a moon to the moon; Farmaps waxing and waning regularly, but appearing 13 times pears a as big, and affording her 13 times as much light as the moon to does us. When the changes to us the earth appears our moon. full to her; and when she is in her first quarter to us, the earth is in its third quarter to her; and vice verfa.

But from one half of the moon the carth is never feen at all: from the middle of the other half, it is always feen over head; turning round almost 30 times as quick as the moon does. From the circle which limits our view of the moon, only one half of the earth's fide next her is feen; the other half being hid below the horizon of all places on that circle. To her the earth feems to be the biggest body in the universe: for it appears 13 times as big as she does to us.

As the earth turns round its axis, the feveral continents, feas, and island, appear to the moon's inhabitants like fo many spots of different forms and brightnels, moving over its furface; but much fainter at lone times than others, as our clouds cover them or leave them. By these spots the Lunarians can determine the time of the earth's diurnal motion, just as we do the motion of the fun: and perhaps they measure their time by the motion of the earth's spots; for they cannot have a truer dial.

The moon's axis is fo nearly perpendicular to the How the ecliptic, that the fun never removes fensibly from her Lunar inequator; and the obliquity of her orbit, which is next can meato nothing as feen from the fun, cannot cause the fun sure their to decline feasibly from her equator. Yet her inhabi-year. tants are not destitute of means for afcertaining the length of their year, though their method and ours must differ. For we can know the length of our year by the return of our equinoxes: but the Lunarians, having always equal day and night, must have recourse to another method; and we may suppose, they measure their year by observing when either of the poles of our earth begins to be enlightened, and the other to disappear, which is always at our equinoxes; they being conveniently fituated for observing great tracts of land about our earth's poles, which are entirely unknown to us. Hence we may conclude, that the year is of the same absolute length both to the earth and moon, though very different as to the number of days, we having 365# natural days, and the Lunarians only 12 70, every day and night in the moon being as long as 29 t on the

The moon's inhabitants on the fide next the earth

Of the moon.

351 Reflects the fun's light,

Longitude

Particular may as casily find the longitude of their places as we Explication can find the latitude of ours. For the earth keeping of the Ce-leftial Phenomena. moon, the east or west distances of places from that meridian are as easily found as we can find our distance from the equator by the altitude of our celestial poles.

As the fun can only enlighten that half of the earth eafily found, which is at any moment turned towards him, and, being withdrawn from the opposite half, leaves it in darknefs, fo he likewife doth to the moon; only with this difference, that as the earth is furrounded by an atmosphere, we have twilight after the sun sets; but if the moon has none of her own, nor is included in that of the earth, the lunar inhabitants have an immediate transition from the brightest funshine to the blackest Fig. 183. darknefs. For, let t r k s w be the earth, and A, B, C, D, E, F, G, II, the moon in eight different parts of her orbit. As the earth turns round its axis from west to cast, when any place comes to t, the twilight begins there, and when it revolves from thence to r the fun S rifes; when the place comes to s the fun fets, and when it comes to w the twilight ends. But as the moon turns round her axis, which is only once a month, the moment that any point of her furface comes to r (fee the moon at G), the fun rifes there without any previous warning by twilight; and when the fame point comes to s the fun fets, and that point goes into darkness as black as at midnight.

Her phases

The moon being an opaque spherical body (for her explained. hills take off no more from her roundness than the inequalities on the furface of an orange takes off from its roundness), we can only see that part of the enlightened half of her which is towards the earth. And therefore, when the moon is at A, in conjunction with the fun S, her dark half is towards the earth, and the difappears, as at a, there being no light on that half to render it vilible. When the comes to her first octant at B, or has gone an eighth part of her orbit from her conjunction, a quarter of her enlightened fide is towards the earth, and the appears horned, as at b. When the has gone a quarter of her orbit from between the earth and fun to C, she shows us one half of her enlightened fide, as at c, and we fay, she is a quarter old. At D, the is in her fecond octant: and by showing us more of her enlightened side she appears gibbous, as at d. At E, her whole enlightened fide is towards the earth; and therefore she appears round, as at e; when we fay it is full moon. In her third octant at F, part of her dark fide being towards the carth, the again appears gibbous, and is on the decrease, as at f. At G, we see just one half of her enlightened tide; and the appears half decreased, or in her third quarter, as at g. At H, we only see a quarter of her culightened side, being in her fourth octant; where the appears horned, as at b. And at A, having completed her course from the fun to the fun again, she disappears; and we say it is new moon. Thus, in going from A to E, the moon feems continually to increase; and in going from E to A, to decrease in the same proportion; having like phases at equal distances from A to E, but as Icen from the fun S fhe is when ys full.

The man appears not perfectly round when she is pears pei- full in ingheft or lowest part of her orbit, because

we have not a full view of her enlightened fide at that Particular time. When full in the highest part of her orbit, a Explication fmall deficiency appears on her lower edge; and the hefial Phecontrary when full in the lowest part of her orbit.

It is plain by the figure, that when the moon changes to the earth, the earth appears full to the moon; and vice verfa. For when the moon is at A, new to the earth, the whole enlightened fide of the earth is towards the moon; and when the moon is at E, full to the earth, its dark fide is towards her. Hence a new moon answers to a full carth, and a full moon to a new earth. The quarters are also reverled to each other.

Between the third quarter and change, the moon is Agreeable frequently visible in the forenoon, even when the fun representashines; and then she affords us an opportunity of see-tion of her ing a very agreeable appearance, wherever we find a phases. globular stone above the level of the eye, as suppose on the top of a gate. For, if the fun shanes on the stone, and we place ourselves so as the upper part of the stone may just feem to touch the point of the moon's lowermost horn, we shall then see the enlightened part of the stone exactly of the same shape with the moon; horned as the is, and inclined the fame way to the horizon. The reason is plain; for the sun calightens, the stone the fame way as he does the moon and both being globes, when we put ourselves into the chove fiture tion, the moon and flone have the lame polition to our eyes; and therefore we must fee a cauch of the minated part of the one as of the start

The position of the moon's curpe, or a light line touching the points of her horns, is any differently inclined to the horizon at different hours of the lame days of her age. Sometimes, the flands, as it were the right on her lower horn, and then fuch a line is pendicular to the horizon: when this happens in what the aftronomers call the monage fuch which is the highest point of the california with the marrix on at that time; and is 90 degrees from both idea. of the horizon, where it is then cut by the ecliptic. But this never happens when the moon is on the meridian, except when the is at the very beginning of Cancer or Capricorn.

That the moon turns round her axis in the time that the goes round her orbit, is quite demonstrable: for, a spectator at rest, without the periphery of the moon's orbit, would fee all her fides turned regularly towards him in that time. She turns round her axis from any star to the same star again in 27 days 8 hours; from the fun to the fun again in 291 days: the former is the length of her fidereal day, and the latter the length of her folar day. A body moving round the fun would have a folar day in every revolution, without turning on its axis; the fame as if it had kept all the while at reft, and the fun moved round it: but without turning round its axis it could never have one fidereal day, because it would always keep the same side towards any given star.

If the earth had no annual motion, the moon would go round it so as to complete a lunation, a sidereal and a folar day, all in the fame time. But, because the earth goes forward in its orbit while the moon goes round the earth in her orbit, the moon muit go as much more than round her orbit from change to change

3,56 Never ap-It Cily round.

Particular in completing a folar day, as the earth has gone for-Explication ward in its orbit during that time, i. c. almost a twelfth of the Ce-part of a circle.

If the carth had no annual motion, the moon's motion round the earth, and her track in open space, would be always the fime (c). But as the earth and Delineation moon move round the fun, the moon's real path in the of her path heavens is very different from her visible path round round the the earth; the latter being in a progressive circle, and the former in a curve of different degrees of concavity. which would always be the fame in the fame parts of the heaven, if the moon performed a complete number of lunations in a year without any fraction.

> Let a nail in the end of the axle of a chariot wheel represent the cartin, and a pin in the nave the moon: if the body of the chariot be propped up to as to keep that whiel from touching the ground, and the wheel be then turned round by hand, the pin will describe a circle both round the nail and in the space it moves through. But if the props be taken away, the horses put to, and the chariot driven over a piece of ground which is circularly convex; the nail in the axle will describe a circular curve, and the pin in the nave will still describe a circle round the progressive nail in the axle, but not in the space through which it moves. In this case, the curve described by the nail will re-temble at ministric as outer of the earth's annual path often word the earth as the pin does round the nail: and the pin will have fome refemblant of the moon's path during fo many lunations.

Fig. 184. Let us now Suppose that the radius of the circular checked by the gail in the axle is to the radius of the chief which the pin in the nave describes round the property of the property of the property of the circular curve A 1234567 B, &c. to the little circle de and then, whill the propreflive nail describes the said curve from A to E, the pin will go once round the nail with regard to the centre of its path, and in fo doing will describe the curve a b c de. The former will be a true reprefentation of the earth's path for one lunation, and the latter of the moon's for that time. Here we may fet aside the inequalities of the moon's motion, and also the earth's moving round its common centre of gravity and the moon's; all which, if they were truly copied in this experiment, would not fenfibly alter the figure of the paths described by the nail and pin, even though they should rub against a plain upright surface all the way, and leave their tracks visible upon it. And if the chariot was driven forward on such a convex piece of ground, fo as to turn the wheel feveral times round, the track of the pin in the nave would flill be concave towards the centre of the circular curve described by the nail in the axle; as the moon's path

is always concave to the fun in the centre of the earth's Paricular 1 voluation

In this diagram, the thickest curve line ABCDE, of the Cawith the numeral figures fet to it, reprefenting as much nomena. of the earth's annual orbit as it describes in 32 days from west to east; the little circles at A, B, C, D, E, show the moon's orbit in due proportion to the earth's; and the smallest curve a C f represents the line of the moon's path in the heavens for 32 days, accounted from any particular new moon at a. The fun is supposed to be in the centre of the curve A 1 2 3 4 5 6 7 B, &c. and the small dotted circles upon it represent the moon's orbit, of which the radius is in the same proportion to the earth's path in this scheme, that the radius of the moon's orbit in the heavens was supposed to bear to the radius of the earth's annual path round the fun; that is, as 240,000 to 81,000,000 or as 1 to

When the earth is at Λ , the new moon is at α ; and in the feven days that the earth describes the curve 1 2 3 4 5 6 7, the moon in accompanying the earth describes the curve ab; and is in her first quarter at b when the earth is at B. As the earth describes the curve B 8 9 10 11 12 13 14, the moon describes the curve be; and is at c, opposite to the fun, when the earth is at C. Whilft the earth deferibes the curve C 15 16 17 18 19 20 21 22, the moon describes the curve ed; and is in her third quarter at d when the earth is at D. And, lastly, Whilst the earth describes the curve D 23 24 25 26 27 28 29, the moon describes the curve de; and is again in conjunction at e with the fun when the earth is at E, between the 20th and 30th day of the moon's age, accounted by the numeral figures from the new moon at A. In describing the curve a Ce, the moon goes round the progressive earth as really as if the had kept in the dotted circle A, and the earth continued immoveable in the centre of that circle.

And thus we see, that although the moon goes Her path round the earth in a circle, with respect to the earth's always concentre, her real path in the heavens is not very differ-cave to the ent in appearance from the earth's path. To show that the moon's path is concave to the fun, even at the time of change, it is carried on a little farther into a fecond

lunation as to f. The curves which Jupiter's fatellites describe are all of different forts from the path described by our moon, although these satellites go round Jupiter as the moon goes round the earth. Let ABCDE, &c. Fig. 185. be as much of Jupiter's orbit as he describes in 18 days from A to T; and the curves a, b, c, d, will be the paths of his four moons going round him in his progreffive motion. Now let us suppose all these moons to fet out from a conjunction with the fun, as feen from Jupiter at A; then, his first or nearest moon will be at a, his fecond at b, his third at c, and his fourth at d. At the end of 24 terrestrial hours after this 3 U 2 conjunction,

(c) In this place, we may confider the orbits of all the satellites as circular, with respect to their primary planets: because the eccentricities of their orbits are too small to effect the phenomena here described.

⁽D) The figure by which this is illustrated is borrowed from Mr Ferguson. Later observations have determined the proportions to be different: but we cannot find that any delineation of this kind hath been given by aftronomers, according to the new proportions.

Particular conjunction, Jupiter has moved to B, his first moon or Explication fatellite has described the curve a 1, his second the of the Celebrate has determed the curve a 1, his recond the lessist Pho-curve b 1, his third c 1, and his fourth d 1. The next nomena. day, when Jupiter is at C, his first fatellite has deforibed the curve a 2 from its conjunction, his second the curve b 2, his third the curve c 2, and his fourth the curve d 2, and fo on. The numeral figures under the capital letters show Jupiter's place in his path every day for 18 days, accounted from A to T; and the like figures set to the paths of his satellites, show where they are at the like times. The first fatellite, almost under C, is stationary at + as seen from the fun, and retrograde from + to 2: at 2 it appears flationary again, and thence it moves forward until it has passed 3, and is twice stationary and once retrograde between 3 and 4. The path of this satellite intersects itfelf every 42 hours, making such loops as in the diagram at 2. 3. 5. 9. 10. 12. 14. 16. 18. a little after every conjunction. The fecond fatellite b, moving flower, barely croffes its path every 3 days 13 hours; as at 4. 7. 11. 14. 18. making only five loops and as many conjunctions in the time that the first makes ten. The third fatellite e moving still slower, and having described the curve c 1. 2. 3. 4. 5. 6. 7. comes to an angle at 7 in conjunction with the fun at the end of 7 days 4 hours; and so goes on to describe such another curve 7. 8. 9. 10. 11. 12. 13. 14. and is at 14 in its next conjunction. The fourth satellite d is always progressive, making neither loops nor angles in the heavens; but comes to its next conjunction at e between the numeral figures 16 and 17, or in 16 days 18 hours.

> The method used by Mr Ferguson to delineate the paths of these fatellites was the following: Having drawn their orbits on a card, in proportion to their relative distances from Jupiter, he measured the radius of the orbit of the fourth fatellite, which was an inch and Too parts of an inch; then multiplied this by 424 for the radius of Jupiter's orbit, because Jupiter is 424 times as far from the fun's centre as his fourth fatellite is from his centre; and the product thence arising was 483 100 inches. Then taking a small cord of this length, and fixing one end of it to the floor of a long room by a nail, with a black lead pencil at the other end, he drew the curve ABCD, &c. and fet off a degree and half thereon from A to T; because Jupiter moves only fo much, whilft his outermost fatellite goes once round him, and somewhat more; so that this small portion of so large a circle differs but very little from a straight line. This done, he divided the space AT into 18 equal parts, as AB, BC, &c. for the daily progress of Jupiter; and each part into 24 for his hourly progress. The orbit of each satellite was also divided into as many equal parts as the fatellite is hours in finishing its synodical period round Jupiter. Then drawthing a right line through the centre of the card, as a diameter to all the four orbits upon it, he put the card son the line of Jupiter's motion, and transferred it needly horary division thereon, keeping always the cie. Cameter line on the line of Jupiter's path; and equal g a pin through each horary division in the or-S'fhe Each fatellite as the card was gradually transfer-

Thing the line ABCD, &c. of Jupiter's motion, full issed points for every hour through the card for aurves described by the satellites, as the primary

planet in the centre of the card was carried forward on Particular the line; and so sinished the figure, by drawing the Explication lines of each fatellite's motion through those (almost in- lastial Phenumerable) points : by which means, this is perhaps as nomena, true a figure of the paths of the fatellites as can be defired. And in the same manner might those of Saturn's fatellites be delineated.

It appears by the scheme, that the three sirst satellites come almost into the same line or position every feventh day; the first being only a little behind with the fecond, and the fecond behind with the third. But the period of the fourth fatellite is so incommensurate to the periods of the other three, that it cannot be gueffed at by the diagram when it would fall again into a line of conjunction with them, between Jupiter and the fup. And no wonder; for supposing them all to have been once in conjunction, it will require 3,087,043,493,260 years to bring them in conjunction

The moon's absolute motion from her change to her first quarter, or from a to b, is so much slower than the earth's, that the falls 240,000 miles (equal to the femidiameter of her orbit) behind the earth at her first quarter in b, when the earth is in B ; that is, the falls quarter in b, when the earth is in B; that is, the falls back a space equal to her distance from the such. From that time her motion is gradually opposition or full at c; and then six as the earth, having regained what the quarter from a to b. From the six as far before the earth at d as the her first quarter in b. But from a tender of retarded so, that the loses as much with reserved as is equal to her distance from the casth as is equal to her distance from the casth at the loses as much with the six and in them in conjunction with the six as a should be that means the six as a should be that means the six as a should be such that the loses are six and the six as a should be such that the six as a should be such th third quarter to her first, and fourter then the less from her first quarter to her third; her path being less curved than the earth's in the former case, and more in the latter. Yet it is flill bent the same way towards the fun; for if we imagine the concavity of the earth's orbit to be measured by the length of a perpendicular line, C g, let down from the earth's place upon the straight line b g d at the full of the moon, and connecting the places of the earth at the end of the moon's first and third quarters, that length will be about 640,000 miles; and the moon when new only approaching nearer to the fun by 240,000 miles than the earth is, the length of the perpendicular let down from her place at that time upon the same straight line, and which shows the concavity of that part of her path, will be about 400,000 miles.

The moon's path being concave to the fun through- A difficulty out, demonstrates that her gravity towards the fun, at concerning her conjunction, exceeds her gravity towards the earth; attraction and if we consider that the quantity of matter in the solved. fun is vastly greater than the quantity of matter in the earth, and that the attraction of each body diminishes as the square of the distance from it increases, we shallfoon find, that the point of equal attraction between. the earth and the fun, is much nearer the earth than. the moon is at her change. It may then appear furprising that the moon does not abandon the earth.

356 Never aprears pericelly

362 Why her

edge ap-

pears al-

WAYS CYCIL

Particular when she is between it and the sun, because she is con-Explication fiderably more attracted by the fun than by the earth of the Co- at that time. But this difficulty vanishes when we confider, that a common impulse on any system of bodies affects not their relative motions; but that they will continue to attract, impel, or circulate round one another, in the same manner as if there was no such impulse. The moon is so near the earth, and both of them so far from the sun, that the attractive power of the fun may be confidered as equal on both; and therefore the moon will continue to circulate round the earth in the same manner as if the sun did not attract them at all: like bodies in the cabin of a ship, which may move round or impel one another in the fame manner when the ship is under fail as when it is at rest: because they are all equally affected by the common motion of the ship. It by any other cause, such as the near approach of a comet, the moon's diffance from the earth should happen to be so much increased, that the difference of their gravitating forces towards the fun should exceed that of the moon towards the earth; in that case, the moon, when in conjunction, would abandon the earth, and be either drawn into the fun or comet, and circulate round about it.

The ruggedocis of the moon's furface mentioned North and their first greatule to us, by reflecting the fun's little in their first the moon were smooth and minimal little statistic paid, for covered with water, she could never indicate the fun's light all round; only in some reflection the fun's light all round; only in some reflection with words from the second never many have wondered to an even the many sections of the moon's discount fundamental to the moon's discount to the weekly the moon of the moon's discount to th tains in force rows will be opposite to the vales in others; and so fill up the inequalities as to make her appear quite round: just as when one looks at an orange, although its roughness be very discernible on the fide next the eye, especially if the sun or a candle shines obliquely upon that fide, yet the line terminating the viable part still appears smooth and even.

Having faid thus much of the moon's Period, Phases, Path, &c. it may not be amiss to describe, in a fummary manner, the irregularities of her motion; and though these have been already treated of on the principles of the Newtonian system, yet as the subject has much embarraffed the astronomical world, it is hoped, that the following explanation of the planetary irregularities upon common mechanical principles, from Mr Nicholfon's Natural Philosophy, may not appear superfluous to uninformed readers.

" If the fun were at rest, and the planets did not mutually gravitate towards each other, they would defcribe ellipses, having the fun in the common focus: But fince they mutually act on the fun and on each other, it must follow that the fun is perpetually moved about the centre of gravity of all the planets; which centre is the common focus of all their orbits. This centre, by maion of the fun's very great hulk, can in no fituation

exceed the distance of its semidiameter from its surface. Particular Some small irregularities arise from these mutual ac-Explication tions, but much less would ensue if the sun were at of the Cerest, or not subject to the reaction of the other planets.

The irregularities in the motions of the common and process. The irregularities in the motions of the primary planets are scarcely considerable enough to come under observation in the course of many revolutions: but those of the moon are very perceptible on account of its nearness to us, and from other causes. It will therefore be fufficient to explain the latter, and apply the explanation to the former, being effects of the fame kind.

"If the actions of the fun upon the earth and moon were equal upon each, according to their maffes, and tended to produce motions in parallel directions, their relative motions would be the same as if no such force acted upon them. But these forces vary both in quantity and direction according to the various relative fituations of the earth and moon.

" Let the point S (fig. 162.) represent the sun, and ADBC the orbit of the moon. Then if the moon be at the quadrature A, the distances ES and AS of the earth and moon from the fun being equal, their gravitics towards S will also be equal, and may be reprefented by those lines ES and AS. Draw the line A parallel and equal to ES, and join LS, which will be parallel to AE. The force AS may be refolved (from principles of compound motion) into the two forces AL and AE; of which AL, by reason of its parallelism and equality to ES, will not diffurb their relative motions or fituation: but the force AE conspiring with that of gravity, will cause the moon to fall farther below the tangent of its orbit than it would have done if no fuch disturbing force had existed. Therefore, at or near the quadratures, the moon's gravity towards the earth is increased more than according to the regular

When the moon is at the conjunction C, the distances ES and CS not being equal, the moon's gravitation towards the fun exceeds that of the earth in the same proportion as the square of ES exceeds the square of CS. And because the excess acts contrary to the direction of the moon's gravity towards the earth, it diminishes the effect thereof, and causes the moon to fall less below the tangent of its orbit than it would if no fuch disturbing force existed. A like and very nearly equal effect follows, when the moon is at the opposition D, by the earth's gravitation towards the sun being greater than that of the moon; whence their mutual gravitation is diminished as in the former cate. Therefore, at or near the conjunction or oppofition, the moon's gravity is diminished, and its orbit rendered less curve.

" It is found that the force added to the moon's gravity at the quadratures, is to the gravity with which it would revolve about the earth in a circle, at its prefent mean distance, if the fun had no effect on its motion, as 1 to 190; and that the force subducted from its gravity at the conjunction or opposition is about double this quantity. The influence of the fun, then, on the whole, increases the moon's distance from the earth, and augments its periodical time: and fince this influence is most considerable when the earth is nearest the fun, or in its perihelium, its periodical time must then be the greatest;" and it is so found by observation.

course, and its orbit is rendered more curve.

"To

"To show the effect of the fun in disturbing the Explication moon's motion at any fituation between the conjunction of the Ce-leftial Phe- and one of the quadratures, suppose at M, let ES renomena. present the earth's gravity towards the fun; draw the line MS, which continue towards G; from M fet off MG, fo that MG may be to ES as the square of the earth's distance ES is to the square of the moon's distance MS; and MG will represent the moon's gravity towards the fun. From M draw MF parallel and equal to ES; join FG, and draw MH parallel and equal to FG. The force MG may be refolved into MF and MH; of which MF, by reason of its parallehim and equality to ES, will not difturb the relative motions or fituations of the moon and earth: MH then is the disturbing force. Draw the tangent MK to the moon's orbit, and continue the radius EM towards I; draw HI parallel to KM, and interfecting Ell in I, and complete the parallelogram by drawing HK parallel to 1M, and interfecting MK in K. The force MH may be refolved into MI and MK; of which MI affects the gravity, and MK the velocity, of the moon. When the force MH coincides with the tangent, that is, when the moon is 35° 16' distant from the quadrature, the force MI, which affects the gravity, vanishes; and when the force MH coincides with the radius, that is, when the moon is either in the conjunction or quadrature, the force MK vanishes. Between the quadrature and the distance of 35° 16' from it, the line or force MH falls within the tangent. and confiquently the force MI is directed towards E, and the moon's gravity is increased: but, at any greater distance from the quadrature, the line MH falls without the tangent, and the force MI is directed from E, the moon's gravity being diminished. It is evident that the force MK is always directed to some point in the line which paffes through the fun and earth; therefore it will accelerate the moon's motion while it is approaching towards that line, or the conjunction, and fimilarly retaid it as it recedes from it, or approaches towards the quadrature, by conspiring with the motion in one case, and subducting from it in the other.

> "As the moon's gravity towards the fun, at the conjunction, is diminished by a quantity which is as the difference of the squares of their distances; and as this difference, on account of the very great diffance of the fun, is nearly the same when the moon is at the opposition, the mutual tendency to separate, or diminution of gravity, will be very nearly the fame. Whence it casily follows, that all the irregularities which have been explained as happening between the quadratures and conjunction, must, in like circumstances, take place between the quadratures and opposition.

> " If the moon revolved about the earth in a circular orbit, the fun's diffurbing influence being supposed not to act, then this influence being supposed to act would convert the orbit into an ellipsis. For the increase of gravity renders it more curve at the quadratures, by caufing the moon to fall further below the tangent; and the diminution of gravity, as well as the increased velocity, render the orbit less curve at the conjunction and opposition, by cauting the moon to fall less below the tangent in a given time. Therefore an ellipsis would be described whose less or more convex parts would be at the quadratures, and whose longest diameter would pass through them: Consequently the

moon would be farthest from the earth at the quadra- Particular tures, and nearest at the conjunction and opposition. "xxx ation Neither is it strange that the moon should approach or of the Cecome nearer to the earth at the time when its gravity nomena. is the leaft, fince that approach is not the immediate confequence of the decrease of gravity, but of the curvity of its orbit near the quadratures; and in like manner, its recess from the earth does not arise immediately from its diminished gravity, from the velocity and direction acquired at the conjunction or opposition. But as the moon's orbit is, independent of the fun's action, an ellipsis, then essees take place only as far as circumstances permit. The moon's gravity towards the earth being thus subject to a continual change in its ratio, its orbit is of no constant form. The law of its gravity being nearly in the, inverse proportion of the fourres of the distances, its orbit is nearly a quiescent ellipsis; but the deviation from this law occasions its apfides to move direct or retrograde, according as those deviations are in defect or in excess. Attronomers, to reduce the motion of the apsides to computation, suppole the revolving body to move in an elliptis, whole transverse diameter, or line of the apsides, revolves at the same time about the focus of the orbit. When the moon is in the conjunction or opposition, the jun fulducts from its gravity, and that the growth or its distance is from the earth; to that its gravity follows a greater proportion than the giverted satio of the square of the distance, and confedently the giving so its orbit must then move interest as a mocal's gravity; and that the more the greater is distance from the earth: so that its gravity follows a left proportion than the inverted ratio of the square of the squ the moon is in the conjunction or opposition, the fun then move in antecedentia or retregrade. But be the action of the fun fubducts, mose from the mose gravity in the conjunction and opposition than at acids to it in the quadratures, the direct motion exceeds the retrograde, and at the end of each revolution the anfides are found to be advanced according to the order. of the figns.

"If the plane of the moon's orbit coincided with that of the ecliptic, these would be the only irregularities arising from the sun's action; but because it is inclined to the plane of the ecliptic in an angle of about 5 degrees, the whole diffurbing force does not act upon the moon's motion in its orbit; a small part of the force being employed to draw it out of the plane of the or-

bit into that of the ecliptic.

" Of the forces MK and MI (fig. 162.) which disturb the moon's motion, MI, being always in the direction of the radius, can have no effect in drawing it out of the plane of its orbit: And if the force MK really coincided with the tangent, as we, neglecting the fmall deviation arifing from the obliquity of the moon's orbit, have hitherto supposed, it is evident that its only effect would be that of accelerating or retarding the moon's motion, without affecting the plane of its orbit: But because that force is always directed to fome point in the line which passes through the centres of the fun and earth, it is evident that it can coincide with the tangent only when that line is in the plane of the moon's orbit; that is to fay, when the nodes are in the conjunction and opposition. At all other

Particular times the force MK must decline to the northward or Explication fouthward of the tangent, and, compounding itself of the Ce-with the moon's motion, will not only accelerate or leftial Pherical retard it, according to the circumflances before exnomena. plained, but will likewife alter its direction, deflecting it towards that fide of the orbit on which the point, the force MK, tends to is fituated. This deflection causes the moon to arrive at the ecliptic either sooner or later than it would otherwife have done; or, in other words, it occasions the intersection of its orbit with the ecliptic to happen in a point of the ecliptic, either nearer to or farther from the moon, than that in which it would have happened if fuch deflection had not taken place.

" To illustrate this, let the elliptical projection COQN (fig. 163.) represent a circle in the plane of the ecliptic, MOPN the moon's orbit interfecting the ecliptic in the nodes N and O. Suppose the moon to be in the northern part of its orbit at M, and moving towards the node O; the disturbing force MK, which tends towards a point in the line SE to the fouthward of the tangent MT, will be compounded with the tangental force, and will cause the moon to describe the arc Mm, to which MR is tangent, inflead of the arc MO; whence the node O is faid to be moved to m. In this manner the motion of the nodes may be ex-

In this manner the motion of the nodes may be explained for any other lituation.

This method evidently depends on a twofold circumitance; we stay, the quantity and direction of the force MK. It the force MK be increased, its direction remained the time, it will deflect the curve of the most than from its orbit in a greater degree; and, on the other hand, if its direction be altered to a sporoscal nearest to a right angle with the tangent, the greatest to a right angle with the tangent, the moon is in the quadrature. The moon is at the other, or it was the moon is at the other, or it was the force MK is the greatest of all and therefore the motion of the nodes is they most confiderable, as far as it depends on nodes is then most considerable, as far as it depends on the quantity of MK: But the direction of this furce in like circumstances depends on the fituation of the line of the nodes. If the line of the nodes coincides with the line paffing through the centre of the fun and earth, the force MK coincides with the tangent of the moon's orbit, and the nodes are stationary; and the farther the node is removed from that line, the farther is that line removed from the plane of the moon's orbit, till the line of the nodes is in the quadratures; at which time the line passes through the centres of the fun and earth, makes an angle with the plane of the moon's orbit equal to its whole inclination, or 5 degrees; consequently, the angle formed between MK and the tangent, in like circumstances, is then greatest, MK being directed to a point in a live which is farther from the plane of the moon's orbit than at any other time, and of course the motion of the nodes is then most considerable.

"To determine the quantity and direction of the motion of the nodes, suppose the moon in the quarter preceding the conjunction, and the node towards which it is moving to be between it and the conjunction; in this case its motion is directed to a point in the ecliptic which is less distant than the point towards which

the force MK is directed: the force MK then com- Particular pounding with the moon's motion, causes it to be di-Explication rected to a point more distant than it would otherwise lessial Fhehave been; that is to fay, the node towards which the nomena. moon moves is moved towards the conjunction. When the moon has passed the node, its course is directed to the other node, which is a point in the ecliptic more diffant than the point to which MK is directed, and therefore MK compounding with its motion causes it to be directed to a point less distant than it would otherwise have been; so that, in this case likewise, the enfuing node is moved towards the conjunction. After the moon has passed the conjunction, the force MK still continues to deflect its course towards the ecliptic; and confequently the motion of the node is the fame way till its arrival at the quadrature. Suppose, again, the moon to be at the conjunction, and the node towards which it is moving to be between it and the quadrature; in this case, the force MK compounding with the moon's motion, causes it to move towards a point in the ecliptic lefs diltant than it would otherwise have done; fo that the enfuing node is brought towards the conjunction.

"When the moon has passed the node, the force MK still continuing to deflect its course towards the fame fide of its orbit, produces a contrary effect; namely, as before it occasioned it to converge to the ecliptic, fo it now causes it to diverge from it; and it? motion, in confequence, tends continually to a point in the ecliptic more diffant than it would otherwise have done; the enfuing node in this inflance being alfo.

brought towards the conjunction.

"As the diffurbing forces are very nearly the fame in the half of the moon's orbit which is farthest from the fun, this last paragraph is true when it moves in that part of its orbit, if the word opposition be everywhere inferted inflead of the word conjunttion.

"Whence it is eafy to deduce this general rule: That when the moon is in the part of its orbit nearest the fun, the node towards which it is moving is made to move towards the conjunction; and when it is in the part of its orbit farthest from the sun, the node towards which it is moving is made to move towards

the opposition.

" Suppose the moon at Q (fig. 176.), or the quadrature preceding the conjunction, then the enfuing node, if at 90° diffance, or at the conjunction C, will be stationary (as before observed); but if it be at a greater or less distance, it will be brought towards C. Thus, if the nodes be in the position MN, the ensuing node M, being at a less distance from Q than 90°, will move towards C, or direct, while the moon moves through the arc QM; after which N becomes the enfuing node, and likewife moves towards the conjunction C, or retrograde during the moon's motion through the arc MR; and because the arc MR exceeds QM, the retrograde motion exceeds the direct. Again, If the nodes be in the position nm, the ensuing node n being at a greater distance from Q than 90°, will move towards C, or retrograde during the moon's motion through the arc Qn; after which the node m becomes the enfuing node, and likewife moves towards the conjunction C, or direct, during the moon's motion through the arc "R; and because the arc Q" ex. ceeds NR, the retrograde motion here also exceeds

Particular the direct. If the nodes be in the quadratures Q R, Explication the enfuing node R removes towards C, or retrograde, of the Ca-during the moon's motion through the arc QR, or leftial Phenomena, almost the whole femiorbit. The same may be shown in the other half of the orbit ROQ with respect to the opposition O; and therefore, in every revolution of the moon, the retrograde motion of the nodes exceeds the direct; and, on the whole, the nodes are carried round contrary to the order of the figns.

> "The line of the conjunction is by the earth's annual motion brought into every possible situation with respect to the nodes in the course of a year, independent of their own proper motion; which last occasions the change of fituation to be performed in about nine-

teen days lefs.

"The inclination of the moon's orbit being the angle which its course makes with the plane of the ecliptic, it is evident from what has been faid, the this angle is almost continually changing. Suppose the line of the nodes, by its retrograde motion, to leave the conjunction C (tig. 175.) and become in the fecond and fourth quarters as in the position MN, and the moon to move from the node M to the node N; then, because the ensuing node N moves towards the conjunction C, while the moon is in the nearer half of its orbit, the moon's course must be continually more and more inflected towards the ecliptic till its arrival at R. This inflection in the first 90°, or MA from M, prevents its diverging to much from the ecliptic as it would otherwise have done; that is to say, it diminishes the angle of the moon's inclination. From A to R its course begins to converge towards the ecliptic; and this convergence is increased by the inflection which in the preceding 90°, prevented its divergence: in the arc A R, then, their inclination is increased. During the moon's motion from R to N, the node is moved towards the opposition O, and consequently the angle of its course to N is rendered less than it would have been if the node has not moved; or, in other words, the inclination is diminished. And because the are MA added to the are RN is greater than the are AR, the inclination at the fubsequent node is less than at the precedent node; and the same may be shown in the other half revolution NQM.

"Therefore, while the nodes are moving from the conjunction and opposition to the quadratures, the inclination of the moon's orbit on the whole diminishes in every revolution till they arrive in the quadratures, at which time it is leaft of all. When the line of the nodes has passed the quadratures, and is in the first and third quarters, as in the polition mn, it is easily shown by the same kind of argument, that the inclination is increased while the moon passes from m to Q, then diminishes for the remainder of the first 90°, or Qa, and is afterwards increased for the other 90°, or an; and the same may be proved for the other half revolution nRm. Consequently, while the nodes are moving from the quadratures to the conjunction and opposition, the inclination is increased by the same degrees as it before was diminished, till they arrive at the conjunction and opposition; at which time it returns to its first quantity, being then greatest of all.

"The line of the nodes in the course of one entire revolution with respect to the sun, is twice in the quadratures, and twice in the conjunction and opposition. Therefore, the inclination of the moon's orbit to the Particular ecliptic is diminished and increased by turns, twice in Explication every revolution of the nodes.

"All the irregularities of the moon's motion are someon a little greater when in the half of its orbit nearest the fun, than when it is in the other half; the chief reafon of which is, that the difference between the fquares of the moon's and earth's distances from the sun is greater in proportion to the fquares themselves, in the former than in the latter case at equal elongations from the quadrature; and consequently the disturbing forces must be more considerable.

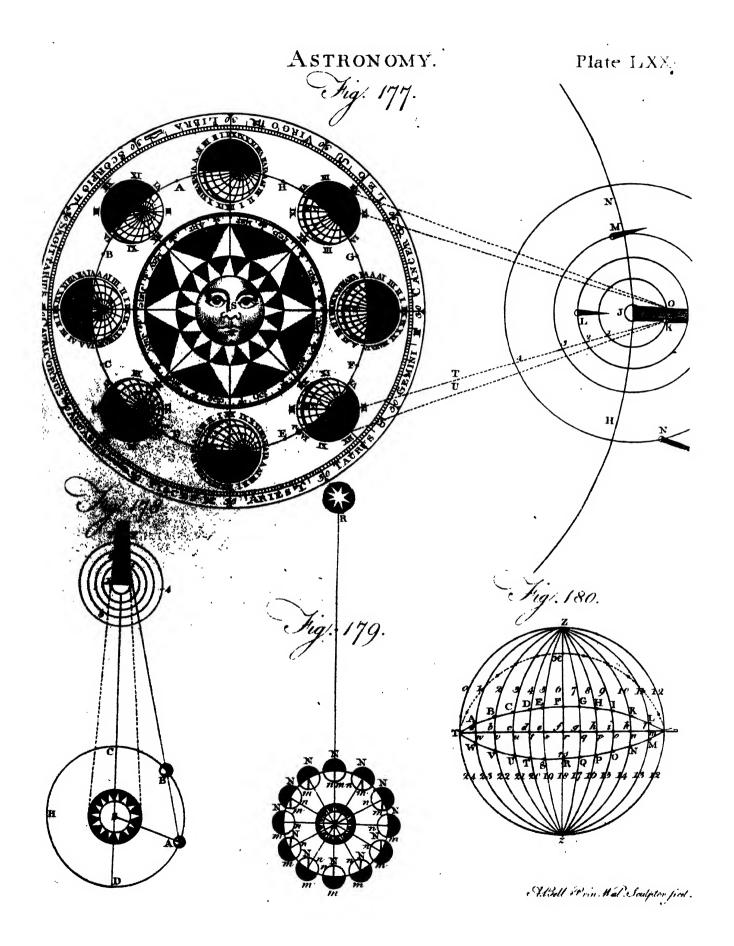

46 Although the moon in reality revolves about the common centre of gravity between her and the earth, and not about the earth itself, and consequently their motions and irregularities are fimilar, and not confined to the moon alone; yet it may be cafily conceived, that the conclusions are not affected in any degree that may be here regarded, when, for the fake of concifenefs, we suppose one of the two bodies to be quickent, and the other to revolve about it.

" Irregularities of the same kind take place among the primary planets, by their mutual actions on each other; but the quantities are not confidenable. Mence

other; but the quantities are not confidenable. Mence the apildes of the planets are found to move in confequentia, but so very flowly that found have apilded whether they move at all. The motion of the planets of the companion of the companion of the solution of their differences from Santure, to be depart to of their diffences from Sature, to be spine the fun's action upon Gaturn. That planet ther hand at the conjunction, acts upon inpiter and the lun in the fame direction; and therefore diffushe their relative position only so far as its actions on each are not equal. The difference of these actions is found, by the same principles, to be Tolly of Jupiter's whole gravity."

SECT. VI. Of the Ebbing and Flowing of the Sea, and the Phenomena of the Harvest and Horizontal Moon.

THE cause of the tides was discovered by Kepler, Cause of who, in his Introduction to the Physics of the Heavens, the tides thus explains it: " The orb of the attracting power discovered which is in the moon, is extended as far as the earth; by Kepler. and draws the waters under the torrid zone, acting upon places where it is vertical, infenfibly on confined feas and bays, but fenfibly on the ocean, whose beds are large, and where the waters have the liberty of reciprocation, that is, of rising and falling." And in the 70th page of his Lunar Astronomy-" But the cause of the tides of the fea appears to be the bodies of the fun and moon drawing the waters of the fea." This hint being given, the immortal Sir Isaac Newton improved it,

bhing and and wrote so amply on the subject, as to make the lowing of theory of the tides in a manner quite his own, by distortion of the covering the cause of their rising on the side of the earth opposite to the moon. For Kepler helicved that the presence of the moon occasioned an impulse which

caused another in her absence.

It has been already observed, that the power of gravity diminishes as the square of the distance increases; and therefore the waters at R on the fide of the earth Fig. 189. ABCDEFGH next the moon M, are more attracted than the central parts of the earth O by the moon, and the central parts are more attracted by her than the waters on the opposite side of the earth at n: and therefore the distance between the earth's centre and the waters on its furface under and opposite to the moon will be increased. For, let there be three bodies at H, O, and D: if they are all equally attracted by the body M, they will all move equally fast towards it, their mutual distances from each other continuing the same. If the attraction of M is unequal, then that body which is most strongly attracted will move fastest, and this will increase its distance from the other body. Therefore, by the law of gravitation, M will attract H more firongly than it does O, by which the distance between H and O will be increased; and a spectator on O will perceive Heifing higher toward Z. In like manner, O being more through attracted than D, it will move farther towards M than D does: confequently, the diflance between D and D will be increased; and a spectator of D and perceiving his own motion, will see D receding seeing from him towards a; all effects and appearances being the same, whether D recedes from O, or O from D.

Suppose new there is a number of bodies, as A, B, C. D, E, F, O, H, pasted round O, so as to form a flexible or fluid ring; then, as the whole is attracted towards M, the parts at H and D will have their different flows. O increased, whilst the parts at B and F being nearly at the same distance from M as O is, these parts will not recede from one another; but rather, by the oblique attraction of M, they will approach nearer to O. Hence the fluid ring will form itself into an elliple ZIBLnKFNZ, whole larger axis nOZ produced will pass through M, and its shorter axis BOF will terminate in B and F. Let the ring be filled with fluid particles, so as to form a sphere round O; then, as the whole moves towards M, the fluid sphere being lengthened at Z and n, will assume an oblong or oval form. If M is the moon, O the earth's centre, ABC DEFGH the sea covering the earth's surface, it is evident, by the above reasoning, that whilst the earth by its gravity falls towards the moon, the water directly below her at B will swell and rife gradually towards her; also the water at D will recede from the centre [strictly speaking, the centre recedes from D], and rife on the opposite side of the earth; whilst the water at B and F is depressed, and falls below the former le-

Vol. II. Part II.

vel. Hence as the earth turns round its axis from the Ebbing and moon to the moon again in 24½ hours, there will be flowing of two tides of flood and two of ebb in that time, as we find by experience.

As this explanation of the ebbing and flowing of the Why the fea is deduced from the earth's constantly falling to-tides are wards the moon by the power of gravity, some may high at full find a difficulty in conceiving how this is possible, when moon. the moon is full, or in opposition to the sun; since the earth revolves about the fun, and must continually fall towards it, and therefore cannot fall contrary ways at the fame time: or if the earth is constantly falling towards the moon, they must come together at last. To remove this difficulty, let it be confidered, that it is not the centre of the earth that describes the annual orbit round the fun, but the (E) common centre of gravity of the earth and moon together: and that whilst the earth is moving round the fun, it also describes a circle round that centre of gravity; going as many times round it in one revolution about the fun as there are lunations or courses of the moon round the earth in a year: and therefore the earth is constantly falling towards the moon from a tangent to the circle it describes round the faid common centre of gravity. Let M be Fig. 190. the moon, TW part of the moon's orbit, and C the centre of gravity of the earth and moon; whilst the moon goes round her orbit, the centre of the earth describes the circle d g e round C, to which circle g a k is a tangent; and therefore when the moon has gone from M to a little past W, the earth has moved from g to e; and in that time has fallen towards the moon, from the tangent at a to e: and fo on, round the whole

The fun's influence in raifing the tides is but small influence of in comparison of the moon's; for though the earth's the sun in diameter bears a considerable proportion to its distance raising from the moon, it is next to nothing when compared tides. to its distance from the sun. And therefore the difference of the sun's attraction on the sides of the earth under and opposite to him, is much less than the difference of the moon's attraction on the sides of the earth under and opposite to her; and therefore the moon must raise the tides much higher than they can be raised by the sun.

On this theory, the tides ought to be highest direct. Why they ly under and opposite to the moon; that is, when the are not moon is due north and south. But we find, that in highest open seas, where the water flows freely, the moon M when the is generally past the north and south meridian, as at p, the meriwhen it is high water at Z and at n. The reason is dian. obvious: for though the moon's attraction was to cease altogether when she was past the meridian, yet the motion of ascent communicated to the water before that time would make it continue to rise for some time aster; much more must it do so when the attraction is only diminished; as a little impulse given to a moving ball will cause it still to move farther than otherwise it

(E) This centre is as much nearer the earth's centre than the moon's as the earth is heavier, or contains a greater quantity of matter than the moon, namely, about 40 times. If both bodies were suspended on it, they would hang in equilibrio. So that dividing 240,000 miles, the moon's distance from the earth's centre, by 40, the excess of the earth's weight above the moon's, the quotient will be 6000 miles, which is the distance of the common centre of gravity of the earth and moon from the earth's centre.

Thing and could have done; and as experience shows that the flowing of day is hotter about three in the afternoon, than when the Sca. the sun is on the meridian, because of the increase made

to the heat already imparted.

The tides answer not always to the same distance of the moon from the meridian at the same places; but are variously affected by the action of the sun, which brings them on fooner when the moon is in her first and third quarters, and keeps them back later when the is in her fecond and fourth: because, in the former case, the tide raised by the sun alone would be earlier than the tide raifed by the moon; and, in the latter cafe, later.

The moon goes round the earth in an elliptic orbit; and therefore, in every lunar month, she approaches mearer to the earth than her mean distance, and recedes farther from it. When she is nearest, she attracts strongest, and so raises the tides most; the contrary happens when the is farthelt, because of her weaker attraction. When both luminaries are in the equator, and the moon in perigee, or at her least distance from the earth, the raifes the tides highest of all, especially at her conjunction and opposition; both because the equatorial parts have the greatest centrifugal force from their describing the largest circle, and from the concurring actions of the fun and moon. At the change, the attractive forces of the fun and moon being united, they diminish the gravity of the waters under the moon, and their gravity on the opposite side is diminished by means of a greater centrifugal force. At the full, whilft the moon raifes the tide under and opposite to her, the fun, acting in the fame line, raifes the tide under and opposite to him; whence their conjoint effect is the fame as at the change; and, in both cases, occasion what we call the Spring Tides. But at the quarters the fun's action on the waters at O and E diminishes the effect of the moon's action on the waters at Z and N; fo that they rife a little under and opposite to the fun at O and H, and fall as much under and opposite to the moon at Z and N; making what we call the Neap Tides, because the fun and moon then act crosswife to each other. But these tides happen not till some time after; because in this, as in other cases, the actions do not produce the greatell effect when they are at the ftrongest, but some time afterward.

The fun being nearer the earth in winter than in fummer, is of course nearer to it in February and October than in March and September; and therefore the greatest tides happen not till some time after the autumnal equinox, and return a little before the vernal.

The fea, being thus rut in motion, would continue to ebb and flow for several times, even though the fun and moon were annihilated, or their influence should cease: as, if a bason of water were agitated, the water would continue to-move for some time after the bason was left to stand still; or like a pendulum, which, having been put in motion by the hand, continues to make feveral vibrations without any new impulle.

When the moon is in the equator, the tides are equally high in both parts of the lunar day, or time of the moon's revolving from the meridian to the meridian again, which is 24 hours 50 minutes. But as the meon declines from the equator towards either pole,

the tides are alternately higher and lower in places has Ebbing and ving north or fouth latitude. For one of the highest flowing of elevations, which is that under the moon, follows her the Sea. towards the pole to which the is nearest, and the other declines towards the opposite pole; each elevation deferibing parallels as far diffant from the equator, on opposite sides, as the moon declines from it to either fide; and confequently the parallels defembed by thefe elevations of the water are twice as many degrees from one another as the moon is from the equator; increafing their diffance as the moon increases her declination, till it be at the greatest, when the faid parallels are at a mean flate, 47 degrees from one another: and on that day, the tides are most unequal in their heights. As the moon returns towards the equator, the parallels described by the opposite elevations approach towards each other, until the moon comes to the equator, and then they coincide. As the moon declines towards the opposite pole, at equal distances, each elevation deferibes the same parallel in the other part of the lunar day, which its opposite elevation described before. Whilk the moon has north declination, the greatest tides in the northern hemisphere are when she is above the horizon; and the reverse whilst her declination is fouth. Let NESQ be the earth, NSC its axis EQ Fig. 192. the equator, T 25 the tropic of Cancer the tro-193, 194. pic of Capricorn, a b the archic chick, at the anterchic, N the north pole, S the fouth pole, M the moon, F and G the two eminences of interest of learning for a large and d, at N and S, and the large of learning good degrees from the highest. Now the large of learning greatest north declination at M, the largest elevation G under her is on the tropic of Cancer T and the opposite elevation F an the tropic of Capri-corn 1 19; and these two elevations describe the tropics by the earth's diurnal rotation. All places in the northern hemisphere ENO have the highest tides when they come into the polition & at Q under the impon: and the lowest tide when the curth's diarnal rotation carries them into the position aTE, on the side oppofite to the moon; the reverse happens at the same time in the fouthern hemisphere ESQ as is evident to fight. The axis of the tides a C d has now its poles a and d (being always go degrees from the highest elevations); in the arctic and antarctic circles; and therefore it is plain, that at these circles there is but one tide of flood, and one of ebb, in the lunar day. For, when the point a revolves half round to b in 12 lunar hours. it has a tide of flood; but when it comes to the fame point a again in 12 hours more, it has the lowest ebb. In feven days afterward, the moon M comes to the equinoctial circle, and is over the equator EQ, when both elevations describe the equator; and in both hemispheres, at equal distances from the equator, the tides are equally high in both parts of the lunar day. The whole phenomena being reversed, when the moon has fouth declination, to what they were when her declination was north, require no farther description.

In the three last mentioned figures, the earth is orthographically projected on the plane of the meridian; but in order to describe a particular phenomenon, we now project it on the plane of the ecliptic. Let HZON be the earth and sea, FED the equator, Tig. 192 the tropic of Cancer, C the arctic circle, P the north pole, and the curves, 1, 2, 3, &c. 24 meridians or

Ebbing and hour circles, interfecting each other in the poles: flowing of AGM is the moon's orbit, S the fun, M the moon, Z the Sca. the water elevated under the muon, and N the opposite equal elevation. As the lowest parts of the water are always 90 degrees from the highest, when the moon is in either of the tropics (as at M), the elevation Z is on the tropic of Capricorn, and the opposite elevation N on the tropic of Cancer; the low-water circle HCO touches the polar circles at C; and the high-water circle ETP6 goes over the poles at P, and divides every parallel of latitude into two equal fegments. In this cafe, the tides upon every parallel are alternately higher and lower; but they return in equal times; the point T, for example, on the tropic of Cancer, (where the depth of the tide is represented by the breadth of the dark shade), has a shallower tide of flood at T than when it revolves half round from thence to 6, according to the order of the numeral figures; but it revolves as foon from 6 to T as it did from T to 6. When the moon is in the equinoctial, the elevations Z and N are transferred to the equator at O and H, and the high and low-water circles are got into each other's former places; in which case the tides return in unequal times, but are equally high in both parts of the lasar day? for a place at 1 (under D) revolving as formerly, goes from the tet at (under P) than from 11 to 1, be-

To now from 1 to 11 (ander F) than from 11 to 1, beeasile the parallel it describes is out into unequal segments by the light vettor circle HCO; but the points
1 and 12 is a light vettor from the point of the tides
at C, which the light papers the pole of the moon's
orbif the day.

Tides that it is a possess, that as the tides are governed

It is not to be doubted, but that the earth's quick rotation brings the poles of the tides nearer to the poles of the world, than they would be if the earth were at rest, and the moon revolved about it only once a month: for otherwise the tides would be more unequal in their heights and times of their returns, than we find they are. But how near the earth's rotation may bring the poles of its axis and those of the tides together, or how far the preceding tides may affect those which follow, fo as to make them keep up nearly to the fame heights and times of ebbing and flowing, is a problem more fit to be folved by observation than by theory.

Those who have opportunity to make observations, and choose to satisfy themselves whether the tides are really affected in the above manner by the different pofitions of the moon, especially as to the unequal times Ebbing and of their return, thay take this general rule for know- flowing of ing when they ought to be fo affected. When the earth's axis inclines to the moon, the northern tides, if not retarded in their passage through shoals and channels, nor affected by the winds, ought to be greatelt when the moon is above the horizon, least when she is below it, and quite the reverse when the earth's axis declines from her; but in both cases, at equal intervals of time. When the earth's axis inclines tidewife to the moon, both tides are equally high, but they happen at unequal intervals of time. In every lunation the earth's axis inclines once to the moon, once from her, and twice fidewife to her, as it does to the fun every year; because the moon goes round the ecliptic every month, and the fun but once in a year. In fummer, the earth's axis inclines towards the moon when new; and therefore the day tides in the north ought to be highest, and night tides lowest, about the change: at the full, the reverfe. At the quarters, they ought to be equally high, but unequal in their returns: because the earth's axis then inclines fidewife to the moon. In winter, the phenomena are the same at full moon as in summer at new. In autumn the earth's axis inclines fidewife to the moon when new and full; therefore the tides ought to be equally high and uneven in their returns at thefe times. At the first quarter, the tides of flood should be least when the moon is above the horizon, greatest when the is below it; and the reverse at her third quarter. In Ipring, the phenomena of the first quarter answer to those of the third quarter in autumn; and vice verfa. The nearer any tide is to cither of the feafons, the more the tides partake of the phenomena of these seasons; and in the middle between any two of them the tides are at a mean flate between those of both.

In open fea, the tides rife but to very small heights in proportion to what they do in wide-mouthed rivers, opening in the direction of the stream of tide. For in channels growing narrower gradually, the water is accumulated by the opposition of the contracting bank ; like a gentle wind, little felt on an open plain, but ftrong and brisk in a street; especially if the wider end of the freet be next the plain, and in the way of the

The tides are so retarded in their passage thro' dif- Irregulariferent shoals and channels, and other wife so variously nes of tides affected by firiking against capes and heallands, that accounted to different places they happen at all distances of the formoon from the meridian, confequently at all hours of the lunar day. The tide propagated by the moon in the German ocean, when she is three hours past the meridian, takes 12 hours to come from thence to London bridge, where it arrives by the time that a new tide is raifed in the ocean. And therefore, when the moon has north declination, and we should expect the tide at London to be greatest when the moon is abov. the horizon, we find it is leaft; and the contrary when the has fourth declination. At feveral places it is high water three hours before the moon comes to the meridian; but that tide which the moon pushes as it were before her, is only the tide opposite to that which was raifed by her when the was nine hour, past the opposite meridian.

There are no tides in lakes, because they are gene-3 X 2

Ebbing and rally so small, that when the moon is vertical she atflowing of tracts every part of them alike, and therefore by rendering all the water equally light, no part of it can be ranfed higher than another. The Mediterranean and Baltic feas have very small elevations, because the inlets by which they communicate with the ocean are fo narrow, that they cannot, in fo short a time, receive or discharge enough to raise or fink their surfaces sen-

369 Why the not affect the harometer.

Air being lighter than water, and the furface of the moon does atmosphere being nearer to the moon than the surface of the fea, it cannot be doubted that the moon raifes much higher tides in the air than in the fea. And therefore many have wondered why the mercury does not fink in the barometer when the moon's action on the particles of air makes them lighter as the passes over the meridian. But we must consider, that as these particles are rendered lighter, a greater number of them is accumulated, until the deficiency of gravity be made up by the height of the column; and then there is an equilibrium, and confequently an equal pressure upon the mercury as before; so that it cannot be affected by the aerial tides. It is very probable, however, that the stars which are seen through an aerial tide of this kind will have their light more refracted than those which are feen through the common depth of the atmosphere; and this may account for the supposed refractions by the lunar atmosphere that have been sometimes observed.

370 Of the har-

It is generally believed that the moon rifes about 50 west moon, minutes later every day than on the preceding ; but this is true only with regard to places on the equator. In places of confiderable latitude there is a remarkable difference, especially in the harvest time. Here the autumnal full moon rifes very foon after funfet for feveral evenings together. At the polar circles, where the mild feafon is of very fhort duration, the autumnal full moon rifes at funfet from the first to the third quarter. And at the poles, where the fun is for half a year absent, the winter full moons shine constantly without fetting from the first to the third quarter.

All these phenomena are owing to the different angles made by the horizon and different parts of the moon's orbit; and may be explained in the following

The plane of the equinoctical is perpendicular to the earth's axis; and therefore as the earth turns round its axis, all parts of the equinoctial make equal angles with the horizon both at rifing and fetting; fo that equal portions of it always rife or fet in equal times. Confequently, if the moon's motion were equable, and in the equinoctial, at the rate of 12 degrees 11 min. from the fun every day, as it is in her orbit, she would rife and fet 50 minutes later every day than on the preceding; for 12 deg. 11 min. of the equinoctial rife or fet in 50 minutes of time in all latitudes.

But the moon's motion is so nearly in the ecliptic, that we may confider her at prefent as moving in it. Now the different parts of the ecliptic, on account of its obliquity to the earth's axis, make very different Ebbing and angles with the horizon as they rife or fet. Those flowing of parts or figns which rife with the smallest angles fet the Sea. with the greatest, and vice verfa. In equal times, whenever this angle is leaft, a greater portion of the ecliptic rifes than when the angle is larger; as may be feen by elevating the pole of a globe to any confiderable latitude, and then turning it round its axis in the horizon. Confequently, when the moon is in those figns which rife or fet with the fmallest angles, she rifes or fets with the least difference of time; and with the greatest difference in those signs which rise or set with the greatest angles.

Let FUP be the axis of a globe, 25 TR the tropic Fig. 187. of Cancer, L 1 19 the tropic of Capricorn, go EU 19 the ecliptic touching both the tropics, which are 47 degrees from each other, and AB the horizon. The equator, being in the middle between the tropics, is cut by the ecliptic in two opposite points, which are the beginnings of Aries and Libra; K is the hour circle with its index, F the north pole of the globe elevated to a confiderable latitude, suppose 40 degrees above the horizon; and P the south pole depressed as much below it. Because of the oblique polition of the sphere below it; iteraute of the oblique polition of the inhere in this latitude, the ecliptic has the high elevation N gs above the horizon, making the name. NU gs of 73½ degrees with it when Canon it was the meridian, at which time Libra rifes in this had been constant to the meridian and Aries rife; in the latitude of the them the cliptic will have the law all the latitude the horizon, making only an awale. NUL of the degrees with it: which is 47 degrees less than the former angle; equal to the diffunce between the laws of the latitude of the control of the c

count to the diffunce between the tropics.

In northern latitudes, the installed angle stade by the celiptic and horizon is when the rest with time Libra fets; the greates when the state of the which time Aries fets. From the ridge of Aries to the rising of Libra (which is twelve (1) lidereal hours) the angle increases; and from the rising of Libra to the riling of Aries, it decreases in the fame proportion. By this article and the preceding, it appears, that the ecliptic rifes fastest about Aries, and slowest about

Libra.

On the parallel of London, as much of the ecliptic rifes about Pisces and Aries in two hours, as the moon goes through in fix days: and therefore, whilft the moon is in these signs, she differs but two hours in rifing for fix days together: that is, about 20 minutes later every day or night than on the preceding, at a mean rate. But in 14 days afterwards, the moon comes to Virgo and Libra, which are the opposite figns to Pifces and Aries; and then she differs almost four times as much in rifing; namely, one hour and about fifteen minutes later every day or night than the former, whilst the is in these signs.

As the moon can never be full but when she is opposite to the sun, and the sun is never in Virgo and Libra but in our autumnal months, it is plain that the

A) The ecliptic, together with the fixed flars, makes 366; apparent diurnal revolutions about the earth in a r; the fun only 3654. Therefore the flars gain 3 minutes 56 feconds upon the fun every day; fo that a real day contains only 23 hours 56 minutes of mean folar time, and a natural or folar day 24 hours. Hence sidereal hours are 11 minutes 58 seconds shorter than 12 solar.

Harvest moon is never full in the opposite signs, Pisces and and Hori- Aries, but in these two months. And therefore we can have only two full moons in the year, which rife fo near the time of funfet for a week together, as above mentioned. The former of these is called the

371 Why the

harvest moon, and the latter the bunter's moon. Here it will probably be asked, why we never obsame phe- ferve this remarkable rising of the moon but in harvest, nomenon is feeing the is in Pifces and Aries twelve times in the year not observ- besides, and must then rise with as little difference of ed at other time as in harvest? The answer is plain: for in winter these signs rise at noon; and being then only a quarter of a circle distant from the sun, the moon in them is in her first quarter: but when the sun is above the horizon, the moon's rifing is neither regarded nor perceived. In spring these signs rise with the sun, because he is then in them; and as the moon changeth in them at that time of the year, the is quite invilible. In fummer they rife about midnight; and the fun being then three figns, or a quarter of a circle, before them,

the moon is in them about her third quarters when

rifing fo late, and giving but very little light; her rifing

paffes unobserved. And in autumn, these figure, being opposite to the sun rise when he sets, with the moon

opposite to the sun, rise when he sets, with the moon in oppositions of an extended such makes her rising very could be a such and south posses he in the herical such as the collectic makes the same angle sources when Aries rises, as it does never the such as such as a sun of the posses with the horizon all the secretary at any at any at any at any at the proceeding, there are the such as a sun of the proceeding, there are the sun of the sun of the sun of the angle with a sun of the sun of the angle when the sun of the sun

shat reason the more remarkable about the full, until we come to the polar circles, or 66 degrees from the equator i in which latitude the ecliptic and horizon become coincident every day for a moment, at the same fidereal hour (or 3 minutes 56 feconds sooner every day than the former), and the very next moment one half of the ecliptic containing Capricorn, Aquarius, Pifces, Aries, Taurus, and Gemini, rifes, and the oppofite half fets. Therefore, whill the moon is going from the beginning of Capricorn to the beginning of Cancer, which is almost 14 days, she rises at the same sidercal hour; and in autumn just at funfet, because all that half of the coliptic, in which the fun is at that time, fets at the fame fidereal hour, and the opposite half rifes; that ie, 3 minutes 56 feconds of mean solar time, fooner every day than on the day before. So, whilst the moon is going from Capricorn to Cancer, the rifes earlier every day than on the preceding; contrary to what she does at all places between the polar circles. But during the above 14 days, the moon is 24 fidereal hours later in fetting: for the fix figns which rife all at once on the eaftern fide of the horizon are 24 hours in setting on the western side of it.

In northern latitudes, the autumnal full moons are in

Pisces and Aries, and the vernal full moons in Virgo Harvell and Libra; in fouthern latitudes, just the reverse, be- and Horicause the seasons are contrary. But Virgo and Libra rife at as small angles with the horizon in southern latitudes, as Pifces and Aries do in the northern; and therefore the harvest moons are just as regular on one fide of the equator as on the other.

As these figns, which rise with the least angles, set with the greatest, the vernal full moons differ as much in their times of rising every night as the autumnal full moons differ in their times of fetting; and fet with as little difference as the autumnal full moons rife; the one

being in all cases the reverse of the other.

Hitherto, for the fake of plainness, we have supposed the moon to move in the ecliptic, from which the sun never deviates. But the orbit in which the moon really moves is different from the ecliptic; one half being elevated 5 degrees above it, and the other half as much depressed below it. The moon's orbit therefore interlects the ecliptic in two points diametrically opposite to each other; and these intersections are called the Moon's Nodes. So the moon can never be in the ecliptic but when the is in either of her nodes, which is at least twice in every course from change to change, and fometimes thrice: For, as the moon goes almost a whole fign more than around her orbit from change to change; if the passes by either node about the time of change, the will pals by the other in about 14 days after, and come round to the former node two days again before the next change. That node from which the moon begins to afcend northward, or above the ecliptic, in northern latitudes, is called the Ascending Node; and the other the Discending Node, because the moon, when she passes by it, descends below the ecliptic fouthward.

The moon's oblique motion with regard to the ecliptic, causes some difference in the times of her rifing and fetting from what is already mentioned. For when the is northward of the celiptic, the rifes fooner and fets later than if the moved in the ecliptic: and when she is fouthward of the ecliptic, she rifes later and fets fooner. This difference is variable, even in the fame figns, because the nodes shift backward about 192 degrees in the ecliptic every year; and to go round it contrary to the order of figns in 18 years 225 days.

When the ascending node is in Aries, the southern half of the moon's orbit makes an angle of 54 degrees less with the horizon than the ecliptic does, when Aries rifes in northern latitudes: for which reason the moon rifes with less difference of time whilst she is in Pifces and Aries, than she would do if she kept in the ecliptic. But in 9 years and 112 days afterward, the descending node comes to Aries; and then the moon's orbit makes an angle 5 degrees greater with the horizon when Aries rifes, than the ecliptic does at that time; which causes the moon to rife with greater difference of time in Pisces and Aries than if she moved

in the ecliptic.

To be a little more particular: When the ascending node is in Aries, the angle is only 97 degrees in the parallel of London when Aries rifes; but when the descending node comes to Aries, the angle is 204 de. grees. This occasions as great a difference of the

Harvest and Horizontal Moon.

372 of the mioon's

nodes.

373 Long

moon's rifing in the same figns every nine years, as there would be on two parallels 10; degrees from one another, if the moon's course were in the ecliptic.

As there is a complete revolution of the nodes in 187 years, there must be a regular period of all the varie-Revolution ties which can happen in the rifing and fetting of the moon during that time. But this shifting of the nodes never affects the moon's rifing fo much, even in her quickelt defeending latitude, as not to allow us still the benefit of her rifing nearer the time of funfet for a few days together about the full in harvest, than when she

is full at any other time of the year.

At the polar circles, when the fun touches the fummoon light mer tropic, he continues 24 hours above the horizon; in winter at and 24 hours below it when he touches the winter tropic. For the fame reason, the full moon neither riles in fummer nor fets in winter, confidering her as moving in the ecliptic. For the winter full moon being as high in the coliptic as the fummer fun, must therefore continue as long above the horizon; and the fummer full moon being as low in the ecliptic as the winter fun, can no more rife than he does. But thefe are only the two full moons which happen about the tropics, for all the others rife and fet. In fummer, the full moons are low, and their itay is short above the horizon, when the nights are short, and we have least occasion for moon light : in winter they go high, and thay long above the horizon, when the nights are long, and we want the greatest quantity of moon light.

At the poles, one half of the ecliptic never fets, and the other half never rifes; and therefore, as the fun is always half a year in describing one half of the ecliptic, and as long in going through the other half, it is natural to imagine that the fun continues half a year together above the horizon of each pole in its turn, and as long below it; rifing to one pole when he lets to the other. This would be exactly the cafe if there were no refraction: but by the atmosphere's refracting the fun's rays, he becomes visible some days sooner, and continues fome days longer in fight, than he would otherwife do: fo that he appears above the horizon of either pole before he has got below the horizon of the other. And, as he never goes more than 23 th degrees below the horizon of the poles, they have very little dark night; it being twilight there as well as at other places, till the fun be 18 degrees below the horizon. The full moon, being always opposite to the fun, can never be feen while the fun is above the horizon, except when the is in the northern half of her orbit; for whenever any point of the ecliptic rifes, the opposite point sets. Therefore, as the sun is above the liorizon of the north pole from the 20th of March till 23d of September, it is plain that the moon, when full, being opposite to the Iun, must be below the horizon during that half of the year. But when the fun is in the fouthern half of the ecliptic, he never rifes to the north pole; during which half of the year, every full moon happens in some part of the northern half of the celiptic which never fets. Confequently, as the polar Inhabitants never fee the full moon in fummer, they have Ther always in the winter, before, at, and after, the full, fhining for 14 of our days and nights. And when the fun is at his greatest depression below the horizon, being then in Capricorn, the moon is at her third quarter

in Aries, full in Concer, and at the full quarter in Li- Harvest bra. And as the beginning of Aries is the titing point and Horiof the ecliptic, Cancer the highest, and Libra the sctting point, the moon rifes at her first quarter in Anes; is most elevated above the horizon, and full in Cancer; and fets, at the beginning of Libra, in her third quarter, having continued visible for 14 diurnal rotations of the earth. Thus the poles are supplied one half of the winter time with conflant moon light in the fuu's abfence; and only lofe fight of the moon from her third to her first quarter, while she gives but very little light, and could be but of little and foretimes of no ferrice to them. A bare view of the figure will make this plain : in which let S be the fun ; e, the earth in fummer, when its north pole n inclines towards the fun, and E. the earth in winter, when its north pole declines from him. SEN and NWS is the horizon of the north pole, which is coincident with the equator; and, in both these positions of the earth, m as a 19 is the moon's orbit, in which the goes round the earth, according to the order of the letters n b c d, A B C D. When the moon is at a, the is in her third quarter to the earth at e, and just rising to the north pole n; at b she thanges, and is at the greatest height above the horizon, as the fun likewife is; at a fire is in her first quarter, as the fun likewife is; at a she is in her drift quarter, fetting below the horizon; and is lovelled, if under it at d, when apposite to the funding and her indigentened side toward the earth. But there was the four the funds to the north pole includes coward the same from the sun as the north pole includes the funding of the north pole whilst the describes the posterior of the north pole whilst the describes the posterior was at the ecliptic of the posterior from her being and below the horizon derive her periods the major that depressed at the full. But it winter, when when it at E, and its north pole declines from the law the new moon D is at her greatest depression below the new moon D is at her greatest depression below the horizon NWS, and the full moon at B at her greatest height above it; rifing at her first quarter A, and keeping above the horizon till the comes to her third quarter C. At a mean thate the is 231 degrees above the horizon at B and b, and as much below it at D and d, equal to the inclination of the earth's axis F. S 25. or S 19, are, as it were, a ray of light proceeding from the fun to the earth; and shows that when the earth is at e, the fun is above the horizon, vertical to the tropic of Cancer; and when the earth is at E, he is below the horizon, vertical to the tropic of Capri-

The fun and moon generally appear larger when near Horizontal the horizon than when at a diffance from it; for which moon acthere have been various reasons affigued. The follow-counted for ing account is given by Mr Ferruson. "The follow-by Mr Ferruson." ing account is given by Mr Ferguson: "These lumi-guson, naries, although at great distances from the earth, appear floating as it were on the furface of our atmoiphere, HGFfcC; a little way beyond the clouds; of Fig. 1764 which those about F, directly over our heads at E, are nearer us than those about H or c in the horizon HEc. Therefore, when the fun or moon appear in the horizon at e, they are not only feen in a part of the fley which is really farther from us than if they were at any confiderable altitude, as about f; but they are also seen through a greater quantity of air and vapours at c than at f. Here we have two concurring appear-

Moon.

Harvest ances which deceive our imagination, and cause us to and Hori- refer the fun and moon to a greater distance at their riling or letting about c, than when they are confider-, ably high, as at f: first, their seeming to be on a part at the atmosphere at c, which is really farther than f from a spectator at E; and, secondly, their being feen through a groffer medium when at c than when at f, which, by rendering them dimmer, causes us to imagine them to be at a yet greater distance. And as, in both cases, they are seen much under the same angle. we naturally judge them to be largest when they seem farthest from us.

" Any one may fatisfy himself that the moon appears under no greater angle in the horizon than on the meridian, by taking a large sheet of paper, and rolling it up in the form of a tube, of such a width, that, obferving the moon through it when the rifes, the may as it were just fill the tube: then tie a thread round it to keep it of that fize; and when the moon comes to the meridian, and appears much less to the eye, look at her again through the fame tube, and she will all it Just as much, if not more, than she did at her rifing.

" When the full moon is in her perigee, or at her least distance from the earth, she is seen under a larger

least distance from the certh, she is seen under a larger angle, and must therefore appear bigger than when she is full at atter aims. And if that part of the atmosphere with the part of the atmosphere with the more replete with vapours that the state of the much the dimmer; and therefore we have the be still the bigger by referring her to be stated for great sliftance, knowing that no objects where we may far distant can appear big unless they make the superior that distant can appear big unless they make the superior unfatisfactory; and we shall be a superior unfatisfactory; and we shall be supposed unfatisfactory; and the supposed unfatisfactory; and spire into the cause of this phenomenon; and after en-deavouring to find certain reasons, sounded on the principles of physics, they have at last pronounced this phenomenon a mere optical illusion.

46 26 The principal differtations which I have feen. conducing to give any information on this subject, or. helping to throw any light on the same, have been those printed in the Transactions of the Royal Society, the Academy of Sciences at Paris, the German Acts, and Dr Smith's Optics; but as all the accounts which I have met with in these writings any way relative to this subject, have not given me that satisfaction which I have defired, curiofity has induced me to inquire after the cause of this singular phenomenon in a manner fomewhat different from that which others have done before me, and by such experiments and observations as have appeared to me pertinent; some of which have

" 3. I have observed the rising and setting sun near the visible horizon, and near rising grounds elevated above the vifible horizon about half a degree, and found him to appear largest when near to the visible horizon; and particularly a confiderable alteration of his magnitude and light has always appeared to me from the

time of his being in the horizon at rifing, to the time

been as follows, viz.

of his being a degree or two above the horizon, and Harwell the contrary at his fetting; which property I have and Horlendeavoured to receive as a prejudice, and an impofition on my fight and judgment, the usual reasons for this appearance.

" 4. I have also observed that the sun near the horizon appears to put on the figure of a spheroid, having its vertical diameter appearing to the naked eye shorter than the horizontal diameter; and by meafuring those diameters in a telescope, have found the vertical one shorter than the other.

" 5. I have made frequent observations and comparifons of the apparent magnitude of the fun's disk, with objects directly under him, when he has been near the horizon, and with such objects as I have found by measurement to be of equal breadth with the fun's diameter; but in the sudden transition of the eye from the fun to the object, and from the object to the fun,. have always found the fun to appear least; and that when two right lines have been imaginarily produced by the fides of those equal magnitudes, they have not appeared to keep parallel, but to meet beyond the fun.

" 6. From these and other like circumstances, I first began to suspect that a sudden dip of the sun into the horizontal vapours, might fomehow or other be the cause of a sudden apparent change of magnitude, although the horizontal vapours had been difallowed to be able to produce any other than a refraction in a vertical direction; and, reducing things to calculation, found, that from the time when the fun is within a deameter or two of the horizon, to the time when he is a femidiameter below the horizon, the fun's rays become passable through such a length of medium, reckoning in the direction of the rays, that the total quintity of medium (reckoning both depth and denfity) through which the rays pass, being compared with the like total depth and denfity through which they pass at several elevations, it was proportionable to the difference of apparent magnitude, as appearing to the

" 7. This circumstance of sudden increase and decrease of apparent magnitude, and as sudden decrease and increase of light (for they both go together), fromed to me no improbable cause of the phenomenon, although I could not then perceive how fuch vapours might contribute toward enlarging the diameter of the fun in a horizontal direction.

" 8. I therefore examined the fun's disk again and again, by the naked eye and by telescopes, at different altitudes; and, among feveral circumstances, found the folar maculæ to appear larger and plainer to the naked eye, and through a telescope, the fun being near the horizon, than they had appeared the same days when the fun was on the meridian, and to appearance more flrongly defined, yet obscured.

" 9. A little before funfetting, I have often feen the edge of the fun, with fuch protuberances and indentures as have rendered him in appearance a very odd figure s. the protuberances shooting out far beyond, and the indentures preffing into the disk of the fun; and always through a telescope magnifying 55 times, the lower limb has appeared with a red glowing arch beneath it, and close to the edge of the fun, while the other parts have been clear.

" 10. A1

Harveft and Horizontal Moon.

"10. At funfetting, these protuberances and indentures have appeared to slide along the vertical limbs, from the lower limb to the higher, and there vanishing, so as often to form a segment of the sun's upper limb, apparently separated from the disk for a small space of time.

"11. At funrifing I have feen the like protuberances, indentures, and flices, above described; but with this difference of motion, that at surising they sirst appear to rise in the sun's upper limb, and slide or move downward to the lower limb; or, which is the same thing, they always appear at the rising and setting of the sun, to keep in the same parallels of altitude by the telescope. This property has been many times so discernible, even by the naked eye, that I have observed the sun's upper limb to shoot out towards right and left, and move downwards, forming the upper part of the disk and apparent portion of a lesser spheroid than the lower part at rising, and the contrary at setting. Through the telescope this has appeared more plain in proportion to the power of magnifying.

"12. These protuberances and indentures so easily measureable by the micrometer, whilst the telescope wires appeared straight, enabled me to conclude, that certain strata of the atmosphere have different refractive powers; and, lying horizontally across the conical or cycloidal space traced out by the rays between the eye and that part of the atmosphere first touched by the rays, must have been the cause of such apparent protuberances and indentures in a horizontal direction across the sun's vertical limbs; and also that the bottoms of those protuberances and indentures must be considerably enlarged, and removed to appearance farther from the centre of the disk than they would have been had there been no such strata to refract.

" 13. Before funrifing, when the fun has been near the tropic; and the sky, at the utmost extent of the horizon, hath appeared very clear; and when certain fogs have appeared in strata placed alternately between a the hills, and over intervening rivers, valleys, &c. fo as to admit a fight of the rifing fun over those fogs; I have observed with admiration the most distant trees and bushments, which at other times have appeared fmall to the naked eye, but while the fun has been passing along a little beneath the horizon obliquely under them, just before funrifing, when the fun has been thus approaching towards trees and bushments, they have grown apparently very large to the naked eve. and also through a telescope; and they have lost that apparent largeness as the fun has been passed by them. Thus a few trees slanding together on the rising ground, at the distance of a few miles, have appeared to grow up into an apparent mountain. Such apparent mountains formed from trees put on all forms and shapes, as floping, perpendicular, over-leaning, &c. but foon recover their natural appearance when the fun is paffed by them, or got above the horizon.

"14. Mountains themselves, at a distance, sometimes appear larger than at other times. Beasts and cattle in the midst of, and being surrounded with, water, appear pearer to us than when no water surrounds them. Cattle, houses, trees, all objects on the summit of a hill, when seen through a fog, and at a proper distance, appear enlarged. All bodies admit of larger apparent

magnitudes when feen through fome mediums than Harvest others.

" But more particularly,

"15. I took a cylindrical glass-vessel about two seet high; and having graduated its sides to inches. I placed it upright on a table, with a piece of paper under the bottom of the glass, on which paper were drawn parallel right lines at proper distances from each other; and having placed a shilling at the bottom of the vessel, it was nearly as low as the paper. Pouring water into the vessel, and viewing the shilling through the medium of water with one eye, whiss I beheld with the other eye where the edges of the shilling were projected on the paper and its parallels, I found the shilling appear larger at every additional inch depth of the water; and this was the case if either eye was used; and the same when the eye was removed far from the surface or near to it, or in any proportion thereto.

16. I took large vessels; and, filling them with water, placed different bodies at the bottoms of those vessels. It always followed, that the greater depth of water I looked through, in the direction from my eye to the objects in the water, the nearer those objects appeared to me. Thus light bodies appeared more mellow and faint, and dark bodies rather better defined, than out of the water, when they were not deeply immeried. And thus they appeared under whatever directions or positions.

thus they appeared under whatever discussions or pontions I viewed the bodies.

"17. I placed different bodies upder an included fair
water, and immerical my face in the many discussion the
bodies in and through the witter. The same alchoa little hazy at the edges, they appeared annel aslarged, and always larger through a greater which as
water. Thus a failling appeared the bodies is half
a crown, with a red glowing arms as her water to the fun, when the fun thank on the prince to the fun, when the fun thank on the prince to the fun, when the fun thank on the prince to the fun, when they are difficulty in the water.

From these experiments he draws a confirmation of his doctrine, that the appearances treated of arise from the different strata of the atmosphere; and then concludes, that the rays coming from the sun are by the horizontal vapours "first obstructed, and many of them totally absorbed; the rest proceeding with a retarded motion, are thereby first reslected, and then less refracted through the humours of the eye; and, lastly, that hereby the image on the retina becomes enlarged."

SECT. VII. Of drawing a Meridian Line. Of Solar and Sidereal Time, and of the Equation of Time.

THE foundation of all astronomical observations is a knowledge of the exact time when the sun, or any other of the celestial bodies, comes to the meridian; and therefore astronomers have been very attentive to the most proper methods of drawing a meridian line, by which only this can be exactly known. The easiest method of doing this is the following, recommended by Mr Ferguson, and is found a very good method of placing a sun-dial horizontally on its pedestal.

Make four or five concentric circles (fig. 5.), about a Ferguson's quarter of an inch from one another, on a flat board a meridian little line,

Harvest and Herizental Moon.

Bquation little less than the board will contain. Fix a pin pert A Time. &c. pendicularly in the centre, and of fuch a length that its whole shadow may fall within the innermost circle for at least four hours in the middle of the day. The pin ought to be about the eighth part of an inch thick, and to have a round blunt point. The board being fet exactly level in a place where the fun shines, suppose from eight in the morning till four in the afternoon, about which hours the end of the shadow should fall without all the circles; watch the times in the forenoon when the extremity of the shortening shadows just touches the several circles, and there make marks. Then, in the afternoon of the same day, watch the lengthening shadow; and where its end touches the several circles in going over them, make marks also. Lastly. With a pair of compasses, find exactly the middle point, between the two marks on any circle, and draw a firsight line from the centre to that point; which line will be covered at noon by the shadow of a small upright wire, which should be put in the place of the pin. The reafon for drawing feveral circles is, that in cale one part of the day should prove clear, and the other part fameof the day (hould prove clear, and the other part loine-what cloudy, if you mill the time when the point of the filled hould traith one while, you may perhaps catched it is still the backer. The part of the principle shout the backers is about the business flower, the second of the backers is about the business flower, the second of the first the fun filless the second of the backers is the backers of the board;

of the sound of the sound; the sound; the sound; the sound of the seconds the sound of the sound finall hole, but the other's dismeter must be equal to whe tangent of the double diffance of the north fiar from the pole; the diffance of the fights being made radius, Let the file be rivetted to the end of a ftraight ruler; then when you would make use of it, lay the ruler on a horizontal plane, so that the end to which the file is fixed may overhang; then look through the eyelight, moving the inflrument till the north ftar appears to touch the circumference of the hole in the other fight, on the same hand with the girdle of Cassiopeia, or on the opposite side to that whereon the star in the Great Bear's rump is at that time; then draw a line by the udge of the ruler, and it will be a true meridian line.

A meridian line being by either of these methods To find the exactly drawn, the time when the fun or any other exact time of the celefial bodies is exactly in the meridian, may be found by a common quadrant, placing the edge of it along the line, and observing when the sun or other luminary can be feen exactly through its two fights, and noting exactly the time; which, supposing the luminary viewed to be the fun, will be exactly noon, or 12 o'clock; but as the apparent diameter of the fun is pretty large, it ought to be known exactly when his centre is in the meridian, which will be some short

Vol. II. Part II.

of noon.

space after his western limb has arrived at it, and be- Equation fore his eaftern limb comes thither. It will be proper, of Time, and therefore, to observe exactly the time of the two limbs being feen through the lights of the quadrant; and the half of the difference between these times added to the one or subtracted from the other, will give the exact time when the fun's centre is in the meridian. What we fay with regard to the fun, is also applicable to the moon; but not to the stars, which have no fensible diameter. To render this more intelligible, the following short description of the quadrant, and method of taking the altitudes of celeftial bodies by it, is fubjoined.

Let HOX (fig. 195.) be a horizontal line, sup-To take the posed to be extended from the eye at A to X, where altitudes of the fky and earth feem to meet at the end of a long the celeftial and level plain; and let S be the fun. The arc XY bodies. will be the fun's height above the horizon at X, and is found by the instrument EDC, which is a quadrantal board, or plate of metal, divided into 90 equal parts or degrees on its limb DPC; and has a couple of little brass plates, as a and b, with a small hole in each of them, called fight-holes, for looking through, parallel to the edge of the quadrant whereon they stand. To the centre E is fixed one end of a thread F, called the plumb-line, which has a small weight or plummet P fixed to its other end. Now, if an observer holds the quadrant upright, without inclining it to either fide, and fo that the horizon at X is feen through the fightholes a and b, the plumb line will cut or hang over the beginning of the degrees at o, in the edge EC: but if he elevates the quadrant so as to look through the fight-holes at any part of the heavens, suppose to the fun at S; just so many degrees as he elevates the fight-hole b above the horizontal line HOX, so many degrees will the plumb-line cut in the limb CP of the quadrant. For, let the observer's eye at A be in the centre of the celestial are XYV (and he may be said to be in the centre of the sun's apparent and diurnal orbit, let him be on what part of the earth he will), in which are the fun is at that time, suppose 25 degrees high, and let the observer hold the quadrant so that he may fee the fun through the fight-holes; the plumbline freely playing on the quadrant will cut the 25th degree in the limb CP, equal to the number of degrees of the fun's altitude at the time of observation. (N. B. Whoever looks at the fun must have a smoked glass before his eyes, to fave them from hurt. The better way is, not to look at the fun through the fight-holes; but to hold the quadrant facing the eye at a little diflance, and so that, the sun shining through one hole, the ray may be feen to fall on the other.)

By observation made in the manner above directed, Difference it is found, that the stars appear to go round the earth between in 23hours 56 minutes 4 feconds, and the fun in 24 hours; folar and fo that the stars gain three minutes 56 feconds upon sidercal the fun every day, which amounts to one diurnal revo-days. lution in a year; and therefore, in 365 days as meafured by the returns of the fun to the meridian, there are 366 days as measured by the stars returning to it: the former are called folar days, and the latter fidereal.

If the earth had only a diurnal motion, without an annual, any given meridian would revolve from the fun to the sun again in the same quantity of time as from any flar to the fame flar again; because the sun would never change his place with respect to the stars. But,

Sidereal

year con-

tains 366

days.

Equation of as the earth advances almost a degree eastward in its Time, &c. orbit in the time that it turns castward round its axis, whatever star passes over the meridian on any day with the fun, will pass over the same meridian on the next day when the fun is almost a degree short of it; that is, 3 minutes 56 feconds fooner. If the year contained only 360 days, as the ecliptic does 360 degrees, the fun's apparent place, so far as his motion is equable, would change a degree every day; and then the fidereal days would be just 4 minutes shorter than the

> folar. Let ABCDEFGHIKLM (fig. 179.) be the earth's orbit, in which it goes round the fun every year, according to the order of the letters, that is, from west to eaft; and turns round its axis in the fame way from the fun to the fun again in every 24 hours. Let S be the fun, and R a fixed star at such an immense distance, that the diameter of the earth's orbit bears no sensible proportion to that distance. Let Nm be any particular meridian of the earth, and N a given point or place upon that meridian when the earth is at A, the sun S hides the star R, which would always be hid if the earth never removed from A; and confequently, as the earth turns round its axis, the point N would always come round to the fun and ftar at the fame time. But when the earth has advanced, suppose a twelfth part of its orbit, from A to B, its motion round its axis will bring the point N a twelfth part of a natural day, or two hours, fooner to the ftar than to the fun; for the angle of NBn is equal to the angle ASB; and therefore any flar, which comes to the meridian at noon with the fun when the earth is at A, will come to the meridian at 10 in the forenoon when the earth is at B. When the earth comes to C, the point N will have the star on its meridian at 8 in the morning, or four hours fooner than it comes round to the fun; for it must revolve from N to n, before it has the sun in its meridian. When the earth comes to D, the point N will have the star on its meridian at 6 in the morning; but that point must revolve six hours more from N to n, before it has mid-day by the fun; for now the angle ASD is a right angle, and so is NDn: that is, the earth has advanced 90 degrees in its orbit, and must turn go degrees on its axis to carry the point N from the star to the sun; for the star always comes to the meridian when Nm is parallel to RSA; because DS is but a point in respect of RS. When the earth is at E, the star comes to the meridian at 4 in the morning; at F, at two in the morning; and at G, the earth having gone half round its orbit, N points to the ftar R at midnight, it being then directly opposite to the fun; and therefore, by the earth's diurnal motion, the flar comes to the meridian 12 hours before the lun. When the earth is at H, the star comes to the meridian at 10 in the evening; at I, it comes to the meridian at 8, that is, 16 hours before the fun; at K, 18 hours before him; at L, 20 hours; at M, 22; and at A, could with the fun again.
> Thus it is plain, that an absolute turn of the earth

> on its axis (which is always completed when any particular meridian comes to be parallel to its fituation at any time of the day before) never brings the same meridian round from the fun to the fun again; but that the earth requires as much more than one turn on its axis to finish a natural day, as it has gone forward in

that time; which, at a mean flate, is a 365th part of Equation of a circle. Hence, in 365 days, the earth turns 366 Time, &c. times round its axis; and therefore, as a turn of the earth on its axis completes a fidereal day, there must be one fidereal day more in a year than the number of folar days, be the number what it will, on the earth or any other planet; one turn being loft with respect to the number of folar days in a year, by the planet's going round the fun; just as it would be lost to a traveller, who, in going round the earth, would lose one day by following the apparent diurnal motion of the fun; and confequently would reckon one day lefs at his return (let him take what time he would to go round the earth) than those who remained all the while at the place from which he fet out. So if there were two earths revolving equally on their axis, and if one remained at A until the other had gone round the fun from A to A again, that earth which kept its place at A would have its folar and fidereal days always of the fame length; and so would have one solar day more than the other at its return. Hence, if the earth turned but once round its axis in a year, and if that turn was made the same way as the earth goes round the sun, there would be continued day on one fide of the earth,

there would be continual day on one fide of the earth, and continual night on the other.

The earth's motion on its axis bring perfectly, uni-inequality form and equal at all times of the year, the fidereal of folar days are always precifely of an equal terms and fo would the folar or natural days task the earth's orbit were a perfect circle, and to same manual times to its orbit. But the earth's district matter to its orbit, and its annual mattern in an inequal time the fun's apparatus mattern in an inequal to attain the interpretation of the continual; for fometimes he sevolves treef the manual matter and its annual mattern in the manual mattern in an information of the continual interpretation at the regulated clock; and at other more into that the time flags, by an equal adult mack more: fo that the time shown by so equal good and a true sun-dial is never the same but on the rath of April, the 10th of June, the 3 th of August, and the 24th of December. The close, if it goes equality and true all the year round, will be before the fan from the 24th of December till the 15th of April; from that time till the 16th of June, the fun will be before the clock; from the 16th of June till the 31st of August, the clock will be again before the sun; and from thence to the 24th of December, the fun will be faster than the clock.

As the equation of time, or difference between the Equation of time shown by a well regulated clock and a true sun-time exdial, depends upon two causes, namely, the obliquity plained. of the ecliptic, and the unequal motion of the earth in it, we shall first explain the effects of these causes separately confidered, and then the united effects resulting from their combination.

The carth's motion on its axis being perfectly equable, or always at the fame rate, and the plane of the equator being perpendicular to its axis, it is evident that in equal times equal portions of the equator pale over the meridian: and so would equal portions of the ecliptic, if it were parallel to, or coincident with, the equator. But, as the ecliptic is oblique to the equator, the equable motion of the earth carries unequal portions of the ecliptic over the meridian in equal times, the difference being proportionate to the obliquity: and as some parts of the ecliptic are much

Fig. 180.

Rquation of more oblique than others, those differences are un-Time, &c. equal among themselves. Therefore, if two suns should start from the beginning either of Aries or Libra, and continue to move through equal arcs in equal times, one in the equator and the other in the ecliptic, the equatorial sun would always return to the meridian in 24 hours time, as measured by a well regulated clock: but the sun in the ecliptic would return to the meridian fometimes sooner and sometimes later than the equatorial sun; and only at the same moments with him on sour days of the year; namely, the 20th of March, when the sun enters Aries; the 21st of June, when he

> pricora; and to this fictitious fun the motion of a well regulated clock always answers.

> Let Zwz be the earth; ZFRs, its axis; abede, &c. the equator; ABCDE, &c. the northern half of the ecliptic from w to a, on the fide of the globe next the eye; and MNOP, &c. the fouthern half on the opposite side from a to w. Let the points at A, B, C, D, E, F, &c. quite round from w to w again bound equal portions of the ecliptic, gone through in equal times by the real fun; and the at n, b, i, a, e, f, &c. equal portions of the equator described in equal times is the fine; and let Zwin be the meridiant

enters Cancer; the 23d of September, when he enters

Libra; and the 21st of December, when he enters Ca-

times in the filling fan; and set & w. De the meridien.

Affice was a mark children with respect
to the mark that the equation with respect
to the mark that the education make be nearer the
meridian of the second of the equator from or to f; and
the address of the equator from or to f; and
the address of the equator from or to f; and
the address of the equator from or to f; and
the address of the equator of the meridian every
the second of the equator of the meridian every
the second of the equator of the clock, until the
ten his contine to f, and the fichtions to f, which two
particles being equidificant from the meridian, both funs
will define to it precifely at noon by the clock.

while the real fun describes the second quadrant of the ecliptic FGHIKL from Cancer to a, he comes later to the meridian every day than the sicitious sun moving through the second quadrant of the equator from f to a; for the points at G, H, I, K, and L, being farther from the meridian, their corresponding points at g, b, i, and I, must be later of coming to it: and as both suns come at the same moment to the point a, they come to the meridian at the moment

of noon by the clock.

In departing from Libra, through the third quadrant, the real fun going through MNOPQ towards by at R, and the fictitious fun through mnopq towards r, the former comes to the meridian every day fooner than the latter, until the real fun comes to 13, and the fictitious to r, and then they come both to the meridian at the fame time.

Lastly, As the real sun moves equably thro' STUVW, from 19 towards or; and the sections sun thro' stuvw, from r towards or, the former comes later every day to the meridian than the latter, until they both arrive at the point or, and then they make it noon at the same time with the clock.

Having explained one case of the difference of time

shown by a well-regulated clock and a true fun-dial, Equation of and confidered the fun, not the earth, as moving in the Time, &c. ecliptic; we now proceed to explain the other cause of this difference, namely, the inequality of the sun's apparent motion; which is slowest in summer, when the sun is farthest from the earth, and swifted in winter when he is nearest to it. But the earth's motion on its axis is equable all the year round, and is performed from west to east; which is the way that the sun appears to change his place in the ecliptic.

If the sun's motion were equable in the eliptic, the whole difference between the equal time as shown by the clock, and the unequal time as shown by the sun, would arise from the obliquity of the ecliptic. But the sun's motion sometimes exceeds a gree in 24 hours, though generally it is less: and when his motion is slowest, any particular meridian will revolve sooner to him than when his motion is quickest; for it will overtake him in less time when he advances a less space than

when he moves through a larger.

Now, if there were two funs moving in the plane of the ecliptic, so as to go round it in a year; the one describing an equal arc every 24 hours, and the other describing sometimes a less arc in 24 hours, and at other times a larger, gaining at one time of the year what it lost at the opposite; it is evident, that either of these suns would come sooner or later to the meridian than the other, as it happened to be behind or before the other; and when they were both in conjunction, they would come to the meridian at the same moment.

As the real fun moves unequably in the ecliptic, let us suppose a sictitious sun to move equably in a circle coincident with the plane of the ecliptic. Let ABCD (fig. 181.) be the ecliptic or orbit in which the real fun moves, and the dotted circle abcd the imaginary orbit of the fictitious sun; each going round in a year according to the order of letters, or from west to east. Let HIKL be the earth turning round its axis the fame way every 24 hours; and suppose both suns to flart from A and a, in a right line with the plane of the meridian EH, at the same moment: the real sun at A, being then at his greatest distance from the earth, at which time his motion is flowest; and the fictitious sun at a, whose motion is always equable, because his distance from the earth is supposed to be always the fame. In the time that the meridian revolves from H to H again, according to the order of the letters HIKL, the real fun has moved from A to F; and the fictitious with a quicker motion from a to f, through a large arc: therefore, the meridian EH will revolve sooner from H to b under the real sun at F, than from HE to & under the fictitious fun at f; and consequently it will then be noon by the sun-dial sooner than by the clock.

As the real fun moves from A towards C, the swiftness of his motion increases all the way to C, where it
is at the quickest. But notwithstanding this, the sictitious sun gains so much upon the real, soon after his
departing from A, that the increasing velocity of the
real sun does not bring him up with the equally-moving
sicitious sun till the former comes to C, and the latter
to c, when each has gone half round its respective orbit; and then being in conjunction, the meridian EH,
revolving to EK, comes to both suns at the same time,

Calculating and therefore it is noon; by them both at the fame mother Diffant ment.

the Planets.

But the increased velocity of the real sun, now being at the quickeft, carries him before the fictitious one; and therefore, the same meridian will come to the fictitious fun fooner than to the real: for whilft the fictitious fun moves from e to g, the real fun moves through a greater arc from C to G: consequently the point K has its noon by the clock when it comes to k, but not its noon by the fun till it comes to I. And although the velocity of the real fun diminishes all the way from C to A, and the fictitious fun by an equable motion is fill coming nearer to the real fun, yet they are in conjunction till the one comes to A and the other to a, and then it is noon by them both at the same moment.

Thus it appears, that the folar noon is always later than noon by the clock whilst the fun goes from C to A; fooner, whilst he goes from A to C; and at these two points the fun and clock being equal, it is noon by them both at the fame moment.

The point A is called the fun's apogee, because when he is there he is at his greatest distance from the earth; the point C his perigee, because when in it he is at his least distance from the earth : and a right line, as AEC, drawn through the earth's centre, from one of the points to the other, is called the line of the Apfiles.

The diffance that the fun has gone in any time from his apogee (not the diffance he has to go to it, though ever so little) is called his mean anomaly, and is reckoned in figns and degrees, allowing 30 degrees to a fign. Thus, when the fun has gone suppose 174 degrees from his apogee at A, he is faid to be 5 figns 14 degrees from it, which is his mean anomaly; and when he is gone suppose 355 degrees from his apogee, he is faid to be 11 figns 25 degrees from it, although he be but 5 degrees short of A in coming round to it again.

From what was faid above, it appears, that when the fun's anomaly is less than 6 figns, that is, when he is anywhere between A and C, in the half ABC of his arbit, the folar noon precedes the clock moon; but when his anomaly is more than 6 signs, that is, when he is anywhere between C and A, in the half CDA of his orbit, the clock noon precedes the folar. When his anomaly is o figns o degrees, that is, when he is in his apogee at A; or 6 figns o degrees, which is when he is in his perigee at C; he comes to the meridian at the moment that the fictitious fun does, and then it is noon by them both at the fame inflant.

SECT. VIII. Of calculating the Diffunces, Magnitudes, &c. of the Sun, Moon, and Planets.

To find the horizontal parallax.

THIS is accomplished by finding out the horizontal parallax of the body whole diffance you defire to know; that is, the angle under which the femidiameter of the earth would appear provided we could fee it from that body; and this is to be found out in the following manner:

Let BAG (fig. 171.) be one half of the earth, AC Calculating its semidiameter, S the sun, m the moon, and EKOL the Distana quarter of the circle described by the moon in re- cos, &co. of volving from the meridian to the meridian again. Let CRS be the rational horizon of an observer at A, extended to the fun in the heavens; and HAO, his fenfible horizon extended to the moon's orbit. ALC is the angle under which the earth's femidiameter AC is feen from the meon at L; which is equal to the angle OAL, because the right lines AO and CL which include both these angles are parallel. ASC is the angle under which the earth's semidiameter AC is seen from the fun at S: and is equal to the angle OAf, because the lines AO and CRS are parallel. Now, it is found by observation, that the angle OAL is much greater than the angle OAf; but OAL is equal to ALC, and OAf is equal to ASC. Now as ASC is much less than ALC, it proves that the earth's semidiameter AC appears much greater as feen from the moon at L. than from the fun at Sp and therefore the earth is much farther from the fun than from the moon. The quantities of these angles may be determined by observation

in the following manner a

the new sources of the plane of the pure and its adge to the plane of the pure and its adge and the plane of the guines and its adge AD in the maridian: a three plane of the guines and its adge to the maridian is the plane of the guines and its adge and in the maridian is the plane of the guines. The plane of the guines are the plane of the guines and its adge of the movement of the guines and the guines are the guines and the guines are of the guines are the guines and the guines are of the guines and the guines are of the guines are of the guines and the guines are of the guines let the preside time be more to the volves about the case area. dien agent le about en hours all about fourth part round it in a fourth part of the in 6 hours se minuter as from From C, that the earth's centre or pole. But as less from the observer's place on the earth's furface; the maca wil feem to have gone a quartent raund the earth when if comes to the faulible horizon at O; for the indi through the fights of which the is then viewed will be at d, on degrees from D, where it was when the was feen at E. Now lot the exact moment when the moen is feen at O (which will be when she is in or sear the fensible horizon) be carefully noted (a) that it may be known in what time she has gone from E to O; which time subtracted from 6 hours. 12 minutes (the time of her going from E to L) leaves the time of her going from O to L, and affords an easy method for finding the angle OAL (called the moon's horizontal parallam which is equal to the angle ALC) by the following analogy: As the time of the moon's describing the are EO is to 90 degrees, so is 6 hours 12 minutes to the degrees of the arc D d E, which measures the angle EAL; from which subtract on degrees, and there remains the angle OAL, equal to the angle ALC, under which the earth's semidiameter AC is feen from the moon. Now, fince all the angles of a right-lined triangle are equal to 180 degrees, or to two right angite.

⁽G) Here proper allowance must be made for the refraction, which being about 34 minutes of a degree in the horizon, will cause the moon's centre to appear 34 minutes above the horizon when her centre is really in it.

Calculating angles, and the fides of a triangle are always propor-

the Dilan-tional to the fines of the opposite angles, fay, by the ces, &c. of Rule of Three, As the fine of the angle ALC at the moon L, is to its opposite side AC, the earth's semidiameter, which is known to be 3985 miles; so is radius, viz. the fine of 90 degrees, or of the right angle ACI, to its opposite side AI, which is the moon's diffance at L from the observer's place at A on the earth's furface; or, so is the fine of the angle CAL to its opposite side CL, which is the moon's distance from the earth's centre, and comes out at a mean rate to be 240,000 miles. The angle CAL is equal to what OAL wants of 90 degrees.

185 Another method.

Other methods have been fallen upon for determining the moon's parallax; of which the following is recommended as the best, by Mr Ferguson, tho' hitherto it has not been put in practice. "Let two observers be placed under the fame meridian; one in the northern hemisphere and the other in the fouthern, at such a distance from each other, that the erc of the celestial meridian included between their two zeniths may be at least 80 or 90 degrees. Let each observer take the distance of the moon's centre from his zenith, by means of an executing good informent, at the moment of her pulling the medition is and there two zenith diffunces of the mines of the mines of the mines. Then, as the mines of the mines. Then, as the mines of the mines. Then, as the mines of the mines have a strong places to her indicate the mines have a strong bound by the diffunct from the centre of the central meeting mentioned the mines of the celefital meeting. Let mines be mines to the celefital meeting. Let mines be mines to the celefital meeting. Let mines both which laterage we suppose to be accommonded by the observers. As interest me places are on the fame meridian nVECs, and of an exceeding good informent, at the moment of

steele two places are on the fame meridian aVECs, and in different hemispheren, the sum of their latitudes 820 wis their distance from each other. Z is the zenith of Vienna, and z the zenith of the Cape of Good Hope; which two zenkhi are also 82 50' distant from each selies, in the common celestial meridian Zz. To the observer at Vienna, the moon's centre will appear at a in the celestial meridian; and at the fame instant, to the observer at the Cape, it will appear at b. Now suppole the moon's diffance Za from the zenith of Vienna to be 380 1' 53", and her distance 26 from the zenith of the Cape of Good Hope to be 46° 4' 41": the fum of thefe two zenith diffrances (Za+zb) is 84° 6' 34": from which hibtract 82° 50", the distance of Zz between the zeniths of these two places, and there will remain 19 16'34" for the arc ba, or distance between the two apparent places of the moon's centre, as feen from V and from C. Then, supposing the tabular radius to be 10,000,000, the natural line of 38° 1' 53'' (the arc $\mathbb{Z}a$) is 6,100,816, and the natural line of 46° 4' 41'' (the are zb) is 7,202,821: the fum of both thefe fines is 13,363,637. Say therefore, As 13,363,637 is to 10,000,000, fo is 1° 16' 34" to 57' 18", which is the moon's horizontal parallax.

If the two places of observation be not exactly un-

der the same meridian, their difference of longitude Calculating must be accurately taken, that proper allowance may the Distantbe made for the moon's declination whilft she is passing ces, &c. of from the meridian of the one to the meridian of the

The parallax, and consequently the distance and bulk. of any primary planet, might be found in the above manner, if the planet was near enough to the earth, fo as to make the difference of its two apparent places fufficiently fenfible; but the nearest planet is too remote

for the accuracy required.

The fun's distance from the earth might be found Parallax of the same way, though with more difficulty, if his hori- the sun diszontal parallax, or the angle OAS equal to the angle ficult to be ASC (fig. 171.), were not fo fmall as to be hardly found, perceptible, being found in this way to be scarce to seconds of a minute, or the 36oth part of a degree. Hence all astronomers, both ancient and modern, have failed in taking the fun's parallax to a fufficient degree of exactness; but as some of the methods used are very ingenious, and show the great acuteness and fagacity of the ancient aftronomers, we shall here give an account The first method was invented by Hip-Hipparparchus; and has been made use of by Prolemy and church his followers, and many other astronomers. It depends method of on an observation of an eclipse of the moon: And the finding it. principles on which it is founded are, If, In a lunar eclipse, the horizontal parallax of the fun is equal to the difference between the apparent semidiameter of the fun, and half the angle of the conical shadow; which is easily made out in this manner. Let the circle AFG (fig. 87.) represent the sun, and DHC the earth; let DHM be the shadow, and DMC the half angle of the cone. Draw from the centre of the fun the light line Fig. 89. SD touching the earth, and the angle DSC is the apparent femidiameter of the earth, feen from the fun, which is equal to the horizontal parallax of the fun; and the angle ADS is the apparent femidiameter of the fun feen from the earth: 'The external angle ADS is equal to the two internals DMS and DSM, by the 32d Prop. Elem. I. And therefore the angle DSM, or DSC, is equal to the difference of the angles ADS and DMS. 2dly, Half the angle of the cone is equal to the difference of the horizontal parallax of the moon and the apparent semidiameter of the shadow, seen from the earth at the distance of the moon. For let C'TE Fig. 173. be the earth; CME the shadow, which at the distance of the moon being cut by a plane, the fection will be the circle FLK, whose semidiameter is FG, and is seen from the centre of the earth under the angle FTG. But by the 32d Prop. Elem. I. the angle CFT is equal to the two intervals FMT and FTM. Wherefore the angle FMT is the difference of the two angles CFT and GTF: but the angle CFT is the angle under which the femidiameter of the earth is feen from the moon, and this is equal to the horizontal parallax of the moon; and the angle GTF is the apparent femidiameter of the shadow seen from the earth's centre. It is therefore evident that the half angle of the cone is equal to the difference of the horizontal parallax of the moon, and the apparent femidiameter of the shadow feen from the earth. Wherefore, if to the apparent femidiameter of the fun there be added the appnrent semidiameter of the shadow, and from the sum you take away the horizontal parallax of the moon, there

the Planets.

388 This me-

Calculating will remain in the horizontal parallax of the fun; which the Distant therefore, if these were accurately known, would be ces, &c. of likewise known accurately; but none of them can be fo exactly and nicely obtained, as to be sufficient for determining the parallax of the fun; for very small errors, which cannot be cafily avoided in measuring thad infuf- these angles, will produce very great errors in the parallax; and there will be a prodigious difference in the distances of the sun, when drawn from these parallaxes. For example, Suppose the horizontal parallax of the moon to be 60' 15", the semidiameter of the sun 16', and the semidiameter of the shadow 44' 30", we shall conclude from thence, that the parallax of the sun was 15", and his distance from the earth about 13,700 femidiameters of the earth. But if there be an error committed, in determining the femidiameter of the shadow, of 12' in defect (and certainly the femidiameter of the shadow cannot be had so precifely as not to be liable to fuch an error); that is, if instead of 44' 30" we put 44' 18" for the apparent diameter of the shadow, all the others remaining as before, we shall have the parallax of the fun 3", and its distance from the earth almost 70,000 femidiameters of the earth, which is five times more than what it was by the first position. But if the fault were in excess, or the diameter of the fliadow exceeded the true by 12", fo that we should put in 44' 42", the parallax would arise to 27", and the distance of the sun only 7700 of the earth's femidiameters; which is nine times less than what it comes to by a like error in defect. If an error in defect was committed of 15", which is still but a fmall millake, the fun's parallax would be equal to nothing, and his distance infinite. Wherefore, fince from so small mistakes the parallax and distance of the fun vary fo much, it is plain that the distance of the fun cannot be obtained by this method.

Since, therefore, the angle that the earth's femidiameter subtends at the fun, is so small that it cannot be determined by any observation, Aristarchus Samius, an ancient and great philosopher and attronomer, contrived a very ingenious way for finding the angle which the semidiameter of the moon's orbit subtends when feen from the fun: This angle is about 60 times bigger than the former, subtended only by the earth's femidiameter. To find this angle, he lays down the following principles:

From the phases of the moon, it hath been demonstrated, that if a plane passed through the moon's centre, to which the line joining the fun and moon's centre was perpendicular, this plane would divide the illuminated hemisphere of the moon from the dark one: and therefore, if this plane should likewise pass through the eye of a spectator on the earth, the moon would appear bisected, or like a half circle; and a right line drawn from the earth to the centre of the moon would be in the plane of illumination, and confequently would be perpendicular to the right line which joins the centres of the fun and moon. Let S be the fun and T the earth, ALq a quadrant of the moon's or-bit; and let the line SL, drawn from the fun, touch the orbit of the moon in L; the angle TLS will be a right angle: and therefore, when the moon is feen in L, it will appear bisected, or just half a circle. At the fame time take the angle LTS, the elongation of the moon from the fun, and then we shall have the angle LST, its complement to a right angle. But we have Calculating the fide TI., by which we can und the fide ST, the the Dullandiftance of the lun from the earth. the Planets

But the difficult point is to determine exactly the moment of time when the moon is bifected, or in its true dichotomy; for there is a confiderable space of This metime both before and after the dichotomy, nay even in thod infufthe quadrature, when the moon will appear bifected, or ficient. half a circle; fo that the exact moment of bisection cannot be known by observation, as experience tells us: and confequently, the true diffance of the fun from the earth cannot be obtained by this method.

Since the moment in which the true dichotomy happens is uncertain, but it is certain that it happens before the quadrature; Ricciolus takes that point of Ricciolus's time which is in the middle, between the time that the method. phasis begins to be doubtful whether it be bisected or not, and the time of quadrature: but he had done better, if he had taken the middle point between the time when it becomes doubtful whether the moon's fide is concave or ftraight, and the time again when it is doubtful whether it is straight or convex; which point of time is after the quadrature; and if he had done this, he would have found the fun's distance a great

deal more than he has made it.

There is no need to confine this antibodies the phas. Another by fis of a dishetomy or hisection, for the phase of the phase of the performed when the moon has the performed when the performed when the performed the performed that is, the properties the performed that is, the properties the performed that is, the properties the performed that the performed the performed that the performed that the performed the performed that the performed the performed that the perform it, and mark the residue; there say, As and the meter of the moon is to the marker, so is the says the sine of an angle, which is therefore founds; the angle added to, or lubtracted from, a right angle, give the exterior angle of the triangle at the moon a wall have the angle at the earth, which is the clongers observed; which therefore being subducted from the exterior angle, leaves the angle at the fun. And in the triangle SLT, having all the angles and one lide I.T, we can find the other fide ST, the diffance of the fun from the earth. But it is almost impossible to All these determine accurately the quantity of the lunar phasis, methods in fo that there may not be an error of a few feconds sufficient. committed; and confequently we cannot by this method find precisely enough the true distance of the fun. However, from such observations, we are sure that the fun is above 7000 femidiameters of the earth diffant from us. Since therefore the true distance of the fun can neither be found by eclipses nor by the phases of the moon, the astronomers are forced to have recourse to the parallaxes of the planets that are next us, as Mars and Venus, which are fometimes much nearer to us than the fun is. Their parallaxes they endeavour to find by fome of the methods above explained; and if these parallaxes were known, then the parallax and distance of the fun, which cannot directly by any obfervations be attained, would eafily be deduced from them. For from the theory of the motions of the earth and planets, we know at any time the proportion

Fig. 90.

Arittar.

chu-'s method.

Calculating of the distances of the sun and planets from us; and the the diftan- horizontal parallaxes are in a reciprocal proportion to the Planets these distances. Wherefore, knowing the parallax of a planet, we may from thence find the parallax of the fun.

394 Another method tion the purallax of Mlars.

Mars, when he is in an achronycal position, that is, opposite to the sun, is twice as near to us as the sun is: and therefore his parallax will be twice as great. But Venus, when she is in her inferior conjunction with the fun, is four times nearer to us than he is, and her parallax is greater in the same proportion. Therefore, though the extreme fmallness of the fun's parallax renders it unobservable by our senses, yet the parallaxes of Mars or Venus, which are twice or four times greater may become fensible. The astronomers have bestowed much pains in finding out the parallax of Mars; but fome time ago Mars was in his opposition to the fun, and also in his perihelion, and consequently in his nearest approach to the earth: And then he was most accurately observed by two of the most eminent astronomers of our age, who have determined his parallax to have been scarce 30 seconds; from whence it was inferred, that the parallax of the fun is scarce 11 feconds, and his diffance about 19,000 femidiameters of the earth.

From that of Verus.

As the parallex of Venus is still greater than that of Mars, Dr Halley proposed a method by it of finding the different fines to within a 500dth part of the whole. The third fines of phierration were at her transits over the line is an investigation with the content of the greatest appearance by astronomers, but it was found an original with special times of impartment and essential with special country as had been the matter is not yet determined so that the matter is not yet determined for the line of the matter of calculations with special by masses of their transits, is as the point of that limb of the sun. To an observer at B, the point of that limb will be on the meridian,

B, the point of that limb will be on the meridian, to the heaven will be at E, and Vewill appear just within it at S. But at the same Littable to an observer at A, Venus is east of the sun, in the right line AVF; the point s of the fun's limb appears at e in the heaven; and if Venus were then visible, she would appear at F. The angle CVA is the horizontal parallax of Venus, which we feek; and is equal to the opposite angle FVE, whose measure is the are FE. ASC is the fun's horizontal parallax, equal to the opposite angle eSE, whose measure is the are E; and FAe (the same as VAv) is Venus's horizontal parallax from the fun, which may be found by obferving how much later in absolute time her total ingress on the sun is, as seen from A than as seen from B, which is the time she takes to move from V to v in her orbit OVv.

It appears by the table of Venus's motion and the fun's, that at the time of her transit in 1761 she moved 4' of a degree on the fun's disk in 60 minutes of time, and consequently 4" of a degree in one minute of time.

Now let us suppose that A is 90° west of B, so that when it is noon at B it will be fix in the morning at A; that the total ingress as seen from B is at one minute past 12, but that as seen from A it is at seven minutes 30 seconds past six; deduct six hours for the difference of meridians of A and B, and the remainder

will be fix minutes 30 feconds for the time by which Calculating the total ingress of Venus on the sun at S, is later as the Did infeen from A than as feen from B; which time being ces, &c, of converted into parts of a degree, is 26, or the arc Fe of Venus's horizontal parallax from the fun; for as 1 minute of time is to 4 seconds of a degree, so is 6; minutes of time to 26 feconds of a degree.

The times in which the planets perform their annual revolutions about the fun are already known by obfervation .- From these times, and the universal power of gravity by which the planets are retained in their orbits, it is demonstrable, that if the earth's mean distance from the sun be divided into 100,000 equal parts, Mercury's mean distance from the sun must be equal to 38,710 of these parts .- Venus's mean distance from the fun, to 72,333 .- Mars's mean distance, 152,369. - Jupiter's, 520,896-and Saturn's, 954,006. Therefore, when the number of miles contained in the mean distance of any planet from the sun is known, we can by these proportions find the mean distance in miles of all the reft.

At the time of the above-mentioned transit, the earth's distance from the fun was 1015 (the mean distance being here considered as 1000), and Venus's distance from the fun 726 (the mean distance being corfidered as 723), which differences from the mean distances arise from the elliptical figure of the planet's orbit .- Subtracting 726 parts from 1015, there remain 289 parts for Venus's distance from the earth at that time.

Now, fince the horizontal parallaxes of the planets are inversely as their distances from the earth's centre, it is plain, that as Venus was between the earth and the fun on the day of her transit, and consequently her parallax at that time greater than the fun's, if her horizontal parallax was then afcertained by observation, the fun's horizontal parallax might be found, and confequently his distance from the earth.—Thus, suppose Venus's horizontal parallax was found to be 36".3480, then, As the sun's distance 1015 is to Venus's distance 289, so is Venus's horizontal parallax 36".3480 to the sun's horizontal parallax 10".3493 on the day of her transit. And the difference of these two parallaxes, viz. 25".9987 (which may be esteemed 26"), will be the quantity of Venus's horizontal parallax from the

To find the fun's horizontal parallax at the time of his mean distance from the earth, say, As 1000 parts of the fun's mean distance from the earth's centre, is to 1015, his distance therefrom on the day of the transit, fo is 10".3493, his horizontal parallax on that day to 10".5045, his horizontal parallax at the time of his mean distance from the earth's centre.

The fun's parallax being thus (or any other way Method of supposed to be) found, at the time of his mean distance computing from the earth, we may find his true distance there-the sun's from, in femidiameters of the earth, by the following diffunce analogy. As the fine (or tangents of fo small an arc from his parallax. as that) of the fun's parallax 10".5045 is to radius, fo parallax. is unity or the earth's semidiameter to the number of semidiameters of the earth that the sun is distant from its centre; which number, being multiplied by 3985, the number of miles contained in the earth's femidiameter, will give the number of miles by which the fun is distant from the earth's centre.

Then,

Calculating Then, As 200,000, the earth's mean distance from the Distant the sun in parts, is to 38,710, Mercury's mean distance the planers from the fun in parts, fo is the earth's mean diffrance from the fun in miles to Mercury's mean diffance from the fun in miles.-And,

397 Diftances of

398

the fixed

ftars im-

Why they

As 100,000 is to 72,333, so is the earth's mean dithe other stance from the fun in miles to Venus's mean distance planets, from the fun in miles.—Likewife, how found.

As 100,000 is to 152,369, so is the earth's mean distance from the sun in miles to Mars's mean distance from the fun in miles .- Again,

As 100,000 is to 520,096, so is the earth's mean diffance from the fun in miles to Jupiter's mean di-Rance from the fun in miles .- Laftly,

As 100,000 is to 954,006, so is the earth's mean distance from the fun in miles to Saturn's mean distance from the fun in miles.

And thus, by having found the distance of any one of the planets from the fun, we have fufficient data for finding the distances of all the rest. And then from their apparent diameters at these known distances, their real diameters and bulks may be found. According to the calculations made from the transit in 1769, we have given the distance of each of the primary and fecondary planets from one another, and from the fun. in fig. 119. In fig. 153. their proportional bulks are thown, according to former calculations by Mr Ferguson; and in fig. 18. their relative magnitudes according to the latest calculations by Mr Dunn. The proportional distances of the satellites of Jupiter and Saturn, with the magnitudes of the fun, and orbit of our moon, by Mr Ferguson, are represented fig. 186.

Diftance of With regard to the fixed flars, no method of afcertaining their distance bath bitherto been found out. measurable. Those who have formed conjectures concerning them, have thought that they were at least 400,000 times far-

ther from us than we are from the fun.

They are faid to be fixed, because they have been generally observed to keep at the same distances from each other; their apparent diurnal revolutions being caused folely by the earth's turning on its axis. feem to big appear of a fensible magnitude to the bare eye, because naked eye. the retina is affected not only by the rays of light which are emitted directly from them, but by many thousands more, which falling upon our eyelids, and upon the aerial particles about us, are reflected into our eyes fo ftrongly as to excite vibrations not only in those points of the retina where the real images of the stars are formed, but also in other points at some distance round about. This makes us imagine the stars to be much bigger than they would appear if we faw them only by the few rays which come directly from them, fo as to enter our eyes without being intermixed with others. Any one may be fensible of this, by looking at a ftar of the first magnitude through a long narrow tube; which, though it takes in as much of the fky as would hold 1000 fuch stars, yet scarce renders that one visible.

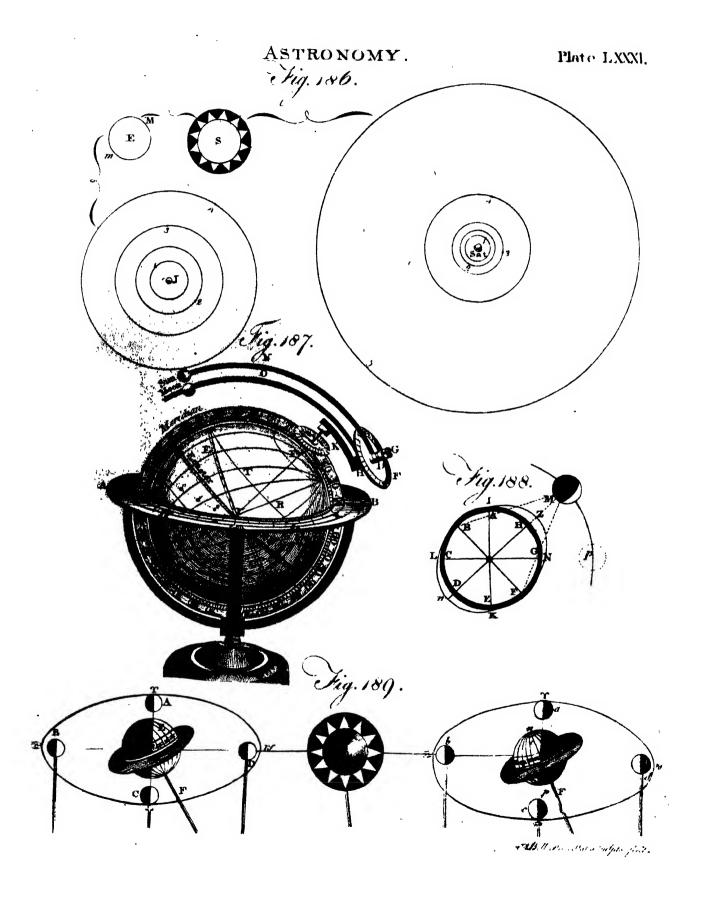

> The more a telescope magnifies, the less is the aperture through which the flar is feen; and confequently, the fewer rays it admits into the eye. Now, fince the ftars appear less in a telescope which magnifies 200 times, than they do to the bare eye, infomuch that they feem to be only indivisible points, it proves at once that the stars are at immense distances from us,

and that they shine by their own proper light. If Calculating they shone by borrowed light, they would be as invi-the Distan fible without telescopes as the satellites of Jupiter are; ces, &c. of the Planets for these satellites appear bigger when viewed with a good telefcope than the largest fixed stars do.

Dr Herschel has proposed a method of ascertaining the parallax of the fixed flars, fomething fimilar, but more complete, than that mentioned by Galileo and others; for it is by the parallax of the fixed stars that we should be best able to determine their distance. The method pointed out by Galileo, and first attempted by Hooke, Flamilead, Molineux, and Bradley, of taking distances of stars from the zenith that pass very near it, has given us a much juster idea of the immense distance of the stars, and furnished us with an approximation to the knowledge of their parallax, that is much nearer the truth than we ever had before. But I)r Herschel mentions the infusiciency of their instruments, which were fimilar to the present zenith sectors, the method of zenith distances being liable to confiderable errors on account of refraction, the change of polition of the earth's axis arising from nutation, precellion of the equinoxes, and other causes, and the aberration of light. The method of his own is by means of double flars; which is exampled from their errors, and of such a nature that the antital parallax, even if it should not exceed the testil mist of a forced, may still become more wisble, and be attestabled, at least to a math greater day at a such a statestabled, at least to a math greater day at a such a such as a such a force of improvement which the relations in a such as the result of micrometers can furnish. The such as a such as the such a such as the paper on the subject.

The such as the such as the such as a such as the interest of the such as t abcrration of light. The method of his own is by flars, according to the theory foljoined. Their two flars ought to be as near each other as possible; and also to differ as much in magnitude as we can find

Dr Herschel's theory of the annual paralless of double stars, with the method of computing from thence what is generally called the parallax of the fixed flare, or of fingle stars of the first magnitude, such as are nearest to us, supposes, first, that the stars, one with another, are about the fize of the fun; and, fecondly, that the difference of their apparent magnitudes is owing to their different distances; so that the star of the second, third, or fourth magnitude, is two, three, or four times as far off as one of the first. These principles which he premises as postulata, have so great a probability in their favour, that they will hardly be objected to by those who are in the least acquainted with the doctrine of chances. Accordingly, let OE (fig. 165.) be the whole diameter of the earth's annual orbit; and let a, b, c, be three stars situated in the ecliptic, in fuch a manner that they may be feen all in one line O abc, when the earth is at O. Let the line Oabe be perpendicular to OE, and draw PE parallel to cO; then, if Oa, ab, bc, are equal to each other, a will be a flar of the first magnitude, b of the second, and

Calculating e of the third. Let us now suppose the angle O a E, he Diffan- or parallax of the whole orbit of the earth, to be I" of

he Planets a degree; then we have PE a= 0 a E=1"; and because very small angles, having the same subtense OE, may be taken to be in the inverse ratio of the lines O a, O b, O c, &c. we shall have O b E= !". O c E= 4", &c. Now when the earth is removed to E, we shall have PEb=Eb==i'', and PEa=PEb=aEb $=\frac{1}{3}$ i. e. the stars a, b, will appear to be $\frac{1}{3}$ distant. We also have PE $c = E c O = \frac{i\pi}{3}$, and PE a - PE c = $a \to c = \frac{1}{3}$; i. c. the stars a, c, will appear to be $\frac{1}{3}$ distant when the earth is at E. Now, since we have $b \text{ EP} = \frac{1}{4}$ ", and $c \text{ EP} = \frac{1}{4}$ ", therefore $b \text{ EP} = c \text{ EP} = \frac{1}{4}$ $b \to c = \frac{1}{4}'' - \frac{1}{4}'' = \frac{1}{6}''$; i. e. the flars b, c, will appear to by only "removed from each other when the earth is at E. Whence we may deduce the following expression, to denote the parallax that will become vifible in the change of distance between the two stars, by the removal of the earth from one extreme of its orbit to the other. Let P express the total parallax of a fixed flar of the first magnitude, M the magnitude of the largest of the two stars, me the magnitude of the smallest, and p the partial parallex to be observed by the change in the distance of a double star; then p=MP; and p, being found by observation, will give E. G. Suppose a star of the shell star of the twelfth suppose star it then will the partial paralless are the star to the be 12×1P or to of the total parallist of a fixed flur of the first magnitude; and if we should, by observation, and the partial parallax between two facilitars to amount to 1", we shall have the total parallex $P = \frac{1 \times 1 \times 12}{12-1} = 1".0909$. If the there are of the third and twenty-fourth magnitude, the partial parallax will be $\frac{24-3}{3\times24} = \frac{21}{72}P$; and if, by observation, p is found to be a tenth of a second, the whole parallax will come out $\frac{\cdot 1 \times 3 \times 24}{24 - 3} = 0'' \cdot 3428$.

Farther, suppose the stars, being still in the ecliptic, to appear in one line, when the earth is in any other part of its orbit between O and E; then will the parallax still be expressed by the same algebraic formula, and one of the maxima will still lie at O, the other at E; but the whole effect will be divided into two parts, which will be in proportion to each other as radius fine to radius + fine of the stars distance from the nearest conjunction or opposition.

When the ftars are anywhere out of the ecliptic, fituated fo as to appear in one line O abc perpendicufar to OE, the maximum of parallax will fill be exprefied by $\frac{m-M}{Mm}$ P; but there will arise another additional parallax in the conjunction and opposition, which will be to that which is found 90° before or after the fun, as the fine (S) of the latitude of the stars Leen at O is to the radius (R); and the effect of this parallax will be divided into two parts; half of it lying on one fide of the large star, the other half on the other fide of it. This latter parallar, moreover, will Vol. II. Part II.

be compounded with the former, fo that the diffance Calculating of the stars in the conjunction and opposition will then the Diffanbe represented by the diagonal of a parallelogram, ce, &c. of whereof the two semiparallaxes are the sides; a general'

expression for which will be $\sqrt{\frac{m-M}{2m!}}$ $\times \frac{SS}{RR} + 1$; for the stars will apparently describe two ellipses in the heavens, whose transverse axis will be to each other in the ratio of M to m (fig. 167.), and A a, B b, C c, D d, will be the cotemporary fituations. Now, if bQ be drawn parallel to AC, and the parallelogram bqBQ be completed, we shall have $bQ = \frac{1}{2}CA - \frac{1}{2}$ ca=1 Cc=1 p, or semiparallax 90° before or after the sun, and B b may be resolved into, or is compound. ed of, bQ and bq; but $bq = \frac{1}{2} BD - \frac{1}{2} b d = \text{the } f_{1}$. miparallax in the conjunction or opposition. We also

have R: S:: $bQ: bq = \frac{pS}{2R}$; therefore the diffance Bb (or Dd) = $\sqrt{\frac{p}{2}} + \frac{p S}{2 R}$; and by fubilitating the value of p into this expression, we obtain

 $\sqrt{\frac{m-M}{2 M mp}}^{\frac{1}{2}} \times \frac{SS}{RR} + 1$, as above. When the flars are in the pole of the ecliptic, b q will become equal to b Q, and B b will be 7071 $P \frac{m-M}{Mm}$. Again, let the stars be at some distance, e.g. 5" from each other, and let them both be in the ecliptic. This case is refolvable into the first; for imagine the star a (sig. 166.) to stand at x, and in that situation the stars x, b, c, will be in one line, and their parallax expressed by $\frac{m-M}{M}$ P. But the angle $a \to x$ may be taken to be equal to a Ox; and as the foregoing formula gives us the angles $x \to b$, $x \to c$, we are to add $a \to x$ or 5" to x E b, and we shall have a E b. In general, let the distance of the stars be d, and let the observed distance at E be D, then will D=d+p, and therefore the whole parallax of the annual orbit will be expressed by $DM_{m} = dM_{m} = P.$ m - M

Suppose the two flars now to differ only in latitude, one being in the ecliptic, the other, c. g. 5 north, when feen at O. This case may also be resolved by the former; for imagine the flars b, c, (fig. 165.) to be elevated at right angles above the plane of the figure, fo that a O b, or a O r, may make an angle of 5" at O; then, instead of the line Oabc, Ea, Eb, Ec, EP, imagine them all to be planes at right angles to the figure; and it will appear that the parallax of the ftars in longitude must be the same as if the small star had been without latitude. And fince the stars b, c, by the motion of the earth from O to E, will not change their latitude, we shall have the following construction for finding the distance of the stars a b, a c, at E, and from thence the parallax B. Let the triangle abs (fig. 168.) represent the situation of the stars; ab is the subtense of 5", the angle under which they are supposed to be seen at O. The quantity $b\beta$ by the former theorem is found, $\frac{m-M}{Mm}P$, which is the partial parallax that would have been feen by the 3 Z carth's

Calculating earth's moving from O to E, if both stars had been in the Diffanthe ecliptic; but on account of the difference in latices, &c. of tinde, it will be now represented by $\alpha \beta$, the hypothethe Planets. neute of the triangle a b &; therefore, in general put-

1)1)— $dd \times Mm$

ting a b = d, and $a \beta = D$, we have = P. Hence D being taken by observation, and d, M, and m, given, we obtain the total parallax.

If the huntion of the flars differs in longitude as well as latitude, we may refolve this cafe by the following method. Let the triangle a b \$ (fig. 169.) represent the fituation of the flars, ab=d being their diffance feen at O, $\alpha \beta = D$ their diffance feen at E. That the change b \$, which is produced by the earth's motion will be truly expressed by $\frac{m-\dot{M}}{Mm}$ P may be proved as

before, by supposing the star a to have been placed at a. Now let the angle of position bau be taken by u micrometer, or by any other method fufficiently exact; then, by folving the triangle a b a, we shall have the longitudinal and latitudinal differences a a an ba of the

two flars. Put
$$a = x$$
, $b = y$, and it will be $x + b\beta$

$$= c q \text{ whence } D = \sqrt{x + \frac{m - MP}{Mm}} + y y \text{; and}$$

$$\frac{\sqrt{1)-3^2\times M} m-xMm}{m-M}=P.$$

If neither of the flars should be in the celiptic, nor have the fame longitude or latitude, the laft theorem will full ferve to calculate the total parallax whose maximum will he in E. There will, moreover, arife another parallax, whole maximum will be in the conjunction and opposition, which will be divided, and lie on different lides of the large flar; but as we know the whole parallax to be exceedingly fmall, it will not be necessary to investigate every particular case of this kind; for by reason of the division of the parallax, which renders observations taken at any other time, except where it is greatest, very unfavourable, the formulæ would be of little use. Dr Herschel closes his account of this theory with a general observation on the time and place where the maxima of parallax will happen.

When two unequal stars are both in the ecliptic, or, not being in the celiptic, have equal latitudes, north or fouth, and the largest star has most longitude; the maximum of the apparent distance will be when the fun's longitude is 90 degrees more than the flars, or when observed in the morning; and the maximum when the longitude of the fun is 90 degrees lefs than that of the stars, or when observed in the evening. When the fmall flar has most longitude, the maximum and minimum, as well as the time of observation will be the reyeife of the former. When the flais differ in latitudes, this makes no alteration in the place of the maximum or minimum, nor in the time of observation; i. e. it is immaterial whether the largest star has the least or the greatest distance of the two stars.

The flars, on account of their apparently various Different magnitudes magnitudes, have been distributed into several classes. of the flar, or orders. Those which appear largest are called flars of the first magnitude; the next to them in luftre, flars of the fecond magnitude : and fo on to the fixth, which

are the smallest that are visible to the bare eye. This Calculating distribution having been made long before the invention the Distanof telefcopes, the flars which cannot be fren without ces, &c. of the affiftance of these instruments are distinguished by the name of telefcopic flars.

The ancients divided the starry sphere into particu-Telescopic lar confiellations, or fystems of stars, according as they stars. lay near one another, fo as to occupy those spaces which the figures of different forts of animals or things would take up, if they were there delineated. And Unformed those stars which could not be brought into any parti-stars. cular confiellation were called unformed flars.

This divition of the flars into different conflellations, Ufes of or afterisms, serves to diffinguish them from one another divither, fo that any particular flar may be readily found fion into in the heavens by means of a celestial globe; on which constellathe conficllations are fo delineated, as to put the most remarkable stars into such parts of the figures as are most easily distinguished. The number of the ancient constellations is 48, and upon our present globes about 70. On Senex's globes are inferted Bayer's letters; the first in the Greek alphabet being put to the biggest ftar in each conftellation, the second to the next, and fo on: by which means, every flar is as eafily found as if a name were given to it. Thus, if the flar y in the constellation of the Ram be mentioned, every astronomer knows as well what flar is meant as if it were pointed out to him in the heavens. See fig. 205, 206. where the ftars are represented with the figures of the animals from whence the confiellations are marked.

There is also a divition of the heavens into three Division of parts. 1. The zodiac (ζωδιακας), from ζωδιως, modium, the heaver an animal," because most of the confiellations in at, Fig. 26. 25 which are 12 in number, have the names of animals: As Aries the ram, Tourus the bull, Gening the Cancer the crab, Leo the lion, Virgo the virgin Libra the balance, Scorpio the scorpion, Sugitturius the afther, Capricol nus the goat, Aquarius the water-bearer, and Pifers the fishes. The zodiac goes quite round the heavens; it is about 16 degrees broad, fo that it takes in the orbits of all the planets, and likewise the orbit of the moon. Along the middle of this zone or belt is the ecliptic, or circle which the earth deferibes annually as feen from the fun, and which the fun appears to describe as seen from the earth. 2. All that region of the heavens which is on the north fide of the zodiac, containing 21 confellations. And, 3. That on the fouth fide, containing 15.

The ancients divided the zodiac into the above 12 Zodiacher conficliations or figus in the following manner: They divided. took a veffel with a fmall hole in the bottom, and, having filled it with water, fuffered the same to distil drop by drop into another veffel fet beneath to receive it; beginning at the moment when some star rose, and continuing till it rose the next following night. The water falling down into the receiver they divided into twelve equal parts; and having two other finall veffels in readiness, each of them fit to contain one part, they again poured all the water into the upper veffel; and, observing the rifing of some star in the zodiac, they at the same time suffered the water to drop into one of the fmall veffels; and as foon as it was full, they shifted it, and fet an empty one in its place. When each veffel was full, they took notice what flar of the zodiac rofe; and though this could not be done

407 Change in cchouc.

The obliquity of the ecliptic to the equinoctial is the obliqui-found at prefent to be above the third part of a degree less than Ptolemy found it. And most of the observers after him found it to decrease gradually down to Tycho's time. If it be objected, that we cannot depend on the observations of the ancients, because of the incorrectness of their instruments; we have to answer, that both Tycho and Flamslead are allowed to have been very good observers; and yet we find that Flamflead makes this obliquity 21 minutes of a degree less than Tycho did about 100 years before him; and as Ptolemy was 1324 years before Tycho, so the gradual decrease answers nearly to the difference of time between these three astronomers. If we consider, that the earth is not a perfect sphere, but an oblate spheroid, having its axis shorter than its equatorial diameter; and that the fun and moon are conflantly acting obliquely upon the greater quantity of matter about the equator, pulling it, as it were, towards a nearer and nearer coincidence with the ecliptic; it will not appear improbable that these actions should gradually diminish the angle between those planes. Nor is it less probable that the mutual attractions of all the planets should have a tendency to bring their orbits to a coincidence: but this change is too small to become sensible in many ages.

> SECT. IX. Of calculating the periodical Times, Places, &c. of the Sun, Moon, and Planets: Delineation of the Phases of the Moon for any particular Time; and the Construction of Astronomical Tables.

> This title includes almost all of what may be called the Practical Part of Astronomy; and as it is by far the most difficult and abstruce, so the thorough investigation of it would necessarily lead us into very deep geometrical demonstrations. The great labours of former astronomers have left little for succeeding ones to do in this respect: tables of the motions of all the celeftial bodies have been made long ago, the periodical time, eccentricities, &c. of the planets determined; and as we suppose few will defire to repeat these laborious operations, we shall here content ourselves with giving some general hints of the methods by which these things have been originally accomplished, that so the operations of the young aftronomer who makes use of tables already formed to his hand may not be merely mechanical.

It hath been already observed, that the foundation Calculating of all astronomical operations was the drawing a me-the Distant ridian line. This being done, the next thing is to find ces, &c. of the Planets. out the latitude of the place where the observations are to be made, and for which the meridian line is drawn. From what hath been faid, No 39, it will eafily be un-Latitude of derstood that the latitude of a place must always beany place equal to the elevation either of the north or fouth pole how found. above the horizon; because when we are exactly on the equator, both poles appear on the horizon. There is, however, no star exactly in either of the celestial poles: therefore, to find the altitude of that invisible point called the Pole of the heavens, we must choose fome flar near it which does not fet; and having by feveral observations, according to the directions given, No 377, found its greatest and least altitudes, divide their difference by z; and half that difference added to the leaft, or subtracted from the greatest, altitude of the flar, gives the exact altitude of the pole, or altitude of the place. Thus, suppose the greatest altitude of the star observed is 60° and its least 50°, we then know that the latitude of the place where the observation was made is exactly 55°.

The latitude being once found, the obliquity of the Obliquity of ecliptic, or the angle made by the fun's annual path the ecliptic with the earth's equator, is easily obtained by the fol-found. lowing method. Observe, about the farmer foldice. the fun's meridian distance from the senith, which is the iun's meridian diffunce from the scrift, which is easily done by a quadrant with a more than index furnished with fights; if this diffunce is diffused from the latitude of the place, provided the latitude of the place of observation, the manner the equator than the place of observation, the remainder will be the obliquity of the celiptic; and figure of observation is nearer the equator than the latitude of observation is nearer the equator than the latitude to be zero 20. to be 23° 29'.

By the same method the declination of the sam spots Sun's decli the equator for any day may be found, and thus a sable nation of his declination for every day of the year might be constructed : thus also the declination of the stars might be found.

Having the declination of the fun, his right aften. His place is fion and place in the ecliptic may be geometrically the ecliptic found by the folution of a case in spherical trigonome-how found try. For let EQ represent the celestial equator, y the Fig. 156. fun, and y X the ecliptic; then, in the right-angled spherical triangle ECy we have the fide Ey, equal to the fun's declination: the angle ECy is always 23° 29', being the angle of the ecliptic with the equator; and the angle yEC is 90°, or a right angle. From these data we can find the side EC the right ascention; and Cy the fun's place in the ecliptic, or his diffance from the equinoctial point; and thus a table of the fun's place for every day in the year, answerable to his declination, may be formed.

Having the fun's place in the ecliptic, the right a-To find th scension of the stars may be found by the help of it, and right ascen a good pendulum clock: for which purpose the mo-lion of the tion of the clock must be so adjusted, that the hand may stars. run through the 24 hours in the fame time that a fer leaving the meridian will arrive at it again; which time is somewhat shorter than the natural day, because of the space the sun moves through in the mean time earl-

Of calculat-ward. The clock being thus adjusted, when the fun ing the pe-is in the meridian, fix the hand to the point from

riodical whence we are to begin to reckon our time; and then the Planets, observe when the star comes to the meridian, and mark the hour and minute that the hand then shows : The hours and minutes described by the index, turned into degrees and minutes of the equator, will give the difference between the right afcention of the fun and ftars; which difference, being added to the right ascension of the fun will give the right ascention of the star. Now, if we know the right alcention of any one flar, we may from it find the right afcentions of all the others which we fee, by marking the time upon the clock between the arrival of the flar whole right alcention we know to the meridian, and another star whose ascension is to be found. This time converted into hours and minutes of the equator, will give the difference of right afcenfions; from whence, by addition, we collect the right afecution of the flar which was to be found out.

Their lonfound.

The right ascension and declination of a star being girudes and known, its longitude and latitude, or diffance from the first star of Aries, and north or fourh from the ecliptic, may thence be eafily found, from the folution of a case in spherical trigonometry, similar to that already mentioned concerning the fun's place; and the places of the fixed flars being all marked in a catalogue according to their longitudes and latitudes, it may thence be conceived how the longitude and latitude comparing its distance from them, and its ap-th may thus be traced; and thus the paths cury and Venus were traced by M. Cassini, though Mr Ferguson made use of an orrery for that

To find the

With regard to the planets, the first thing to be done periodical is to and out their periodical times, which is done by times of the observing when they have no latitude. At that time the planet is in the ecliptic, and confequently in one of its nodes; fo that, by waiting till it returns to the same node again, and keeping an exact account of the time, the periodical time of its revolution round the fun may be known pretty exactly. By the same observations, from the theory of the earth's motion we can find the position of the line of the nodes; and when once the polition of this line is found, the angle of inclination of that planet's orbit to the earth may also be known.

Eccentricity of the mined

The eccentricity of the earth's orbit may be determined by observing the apparent diameters of the fun earth'sorbit at different times : when the fun's diameter is leaft, the how deter- earth is at the greatest distance; and when this diameter is greatest, the earth is at its least distance from him. But as this method must necessarily be precarious, another is recommended by Dr Keill, by observing the velocity of the earth in its orbit, or the apparent velocity of the fun, which is demonstrated to be always reciprocally as the square of the distance.

416 Oftheother planets.

The eccentricities of the orbits of the other planets may be likewife found by observing their velocities at different times; for all of them observe the same proportions with regard to the increase or decrease of their velocity that the earth does; only, in this case, care must be taken to observe the real, not the apparent, velocities of the planets, the last depending on the motion of the earth at the same time. Their aphelia, or points of

their orbits where they are farthest from the sun, may Of calculatbe known by making feweral observations of their di-ing the peflances from him, and thus perceiving when these distances cease to increase. the Planets,

The position of the aphelion being determined, the planet's distance from it at any time may also be found by observation, which is called its true or cocquated anomaly; but by supposing the motion of the planet To find to be regular and uniform, tables of that motion may their places casily be constructed. From thence the planet's mean bits. place in its orbit may be found for any moment of time; and one of these moments being fixed upon as an epocha or beginning of the table, it is easy to underfland, that from thence tables of the planet's place in its orbit for any number of years either preceding or consequent to that period may be constructed. These tables are to be constructed according to the meridian of equal time, and not true or apparent time, because of the inequalities of the earth's motion as well as of that of the planet, and equations must be made to be added to or subtracted from the mean motion of the planet as occasion requires; which will be readily underflood from what we have already mentioned concerning the unequal motion of the earth in its orbit. When all the necessary tables are constructed by this or similar methods, the calculating of the planetary places becomes a mere matter of mechanism, and consists only in the proper additions and fubtractions according to the directions always given along with such tables. It must be observed, however, that the accidental in-Inaccuraterference of the planets with one another by their mu-cies from tual attractions, renders it impossible to construct any the mutual tables that shall remain equally perfect; and therefore attraction of the plafrequent actual observations and corrections of the tables nets. will be necessary. This disturbance, however, is inconfiderable, except in the planets Jupiter, and Saturn, and they are in conjunction only once in 800 years.

the planets, is also applicable to the moon; but with with regard more difficulty, on account of the greater inequalities of to the her motions, the cause of which has been already ex-moon. plained. She indeed moves in an ellipse as the rest do, and its eccentricity may be better computed from observing her diameter at different times than that of the earth's orbit; but that eccentricity is not always the same. The reason of this, and indeed of all the other lunar inequalities, is, that the fun has a fensible effect upon her by his attraction, as well as the earth. Consequently, when the earth is at its least distance from the fun, her orbit is dilated, and the moves more flowly; and, on the contrary, when the earth is in its aphelion, her orbit contracts, and she moves more fwiftly. The eccentricity is always greatest when the line of the apfides coincides with that of the fyzygies, and the earth is at its least distance from the sun. When the moon is in her fyzygies, i. e. in the line that joins the centres of the earth and fun, which is either in her conjunction or opposition, the moves swifter, ceteris paribus, than in the quadratures. According to the dif-ferent distances of the moon from the fyzygies, she changes her motion; from the conjunction to her first quadrature, she moves somewhat slower; but recovers her velocity in the second quarter. In the third quarter she again loses, and in the last again recovers it.

What hath been already mentioned with regard to Difficulties

Meres c-

qually on

her axis.

the Planets

&ε.

Of calcula- The apogeon of the moon is also irregular; being ting the perfound to move forward when it coincides with the line Times of of the fyzygies, and backwards when it cuts that line the Planets, at right angles. Nor is this motion in any degree equal: in the conjunction or opposition, it goes brilkly forwards, and in the quadratures moves either flowly for-

wards, flands full, or goes backwards. The motion of the nodes has been already taken notice of: but this motion is not uniform more than the reft; for when the line of the nodes coincides with that of the fyzygies. they fland flill 4 when their lines cut that at right angles, they go backwards with the velocity, as Sir Ifaac Newton hath shown, of 16" 19" 24"" an hour The only equable motion the moon has, is her revolution on her axis, which the always performs exactly in the space of time in which she moves round the earth. From hence arises what is called the moon's libration ; for as the motion round her axis is equable, and that in her orbit unequal, it follows, that when the moon is in her perigee, where the moves fwiftest, that part of her furface, which on account of the motion in her orbit would be turned from the earth, is not fo, by reason of the motion on her axis. Thus some parts in the limb or margin of the moon fometimes recede from, and fometimes approach towards, the centre of the disk. Yet this equable rotation produces an apparent irregularity; for the axis of the moon not being perpendicular, but a little inclined to its orbit, and this axis maintaining its parallelism round the earth, it mult necessarily change its fituation with refpect to an observer on the earth, to whom sometimes

the one and fometimes the other pole of the moon be-

comes viable; whence it appears to have a kind of

wavering or vacillatory motion. 4:1

I anar iraccounted for by Sir ten.

From all these irregularities it may well be concluded, regularities that the calculation of the moon's place in her orbit is a very difficult mater; and indeed, before Sir Ifaac Had New- Newton, aftronomers in vain laboured to subject the lunar irregularities to any rule. By his labours, however, and those of other astronomers, these difficulties are in a great measure overcome; and calculations with ragard to this luminary may be made with as great Her period certainty as concerning any other. Her periodical deal time time may be determined from the observations of two determined lunar eclipses, at as great a distance from one anoby Coper- ther as possible; for in the middle of every lunar eclipfe, the moon is exactly in opposition to the fun. Compute the time between these two eclipses or oppositions, and divide this by the number of lunations that have intervened, and the quotient will be the fynodical mouth, or time the moon takes to pals from one conjunction to another, or from one opposition to another. Compute the fun's mean motion in the time of the fynodical month, and add this to the entire circle deferibed by the moon. Then, As that fum is to 360°, fo is the quantity of the fynodical month to the periodical, or time that the moon takes to move from one point of her orbit to the same point again. Thus, Copernicus, in the year 1500, November 6th, at 2 hours 20 minutes, observed an eclipse of the moon at Rome; and August 1st 1523, at 4 hours 25 minutes, another

at Cracow: hence the quantity of the fynodical month Of calculating the peis thus determined: riodical Times of

ctermined :	Y.	D.	Н.	M.
Observ. 2d				
Obierv. 1st	1500	310	2	20

Interval of time 292 Add the intercalary ? 5 days for leap years [

Exact interval 22 297 2 5,or11991005'. This interval divided by 282, the number of months elapfed in that time, gives 29 days 12 hours 41 minutes for the length of the fynodical month. But from the observations of two other eclipses, the same author more accurately determined the quantity of the fynodical month to be 29 degrees 11 hours 45 minutes 3 feconds; from whence the mean periodical time of the moon comes to be 27 degrees 7 hours 43 minutes 5 feconds, which exactly agrees with the observations of later aftronomers.

The quantity of the periodical month being given, Her diurna by the Rule of Three, we may find the moon's diurnal and horary and horary motion; and thus may tables of the moon's motion. mean motion be constructed; and if from the moon's mean diurnal motion that of the fun be fubtracted, the remainder will be the moon's mean diurnal motion from the fun.

Having the moon's distance from the fund her phafis for that time may be easily delineated by the following method laid down by Dr Keill. Let the circle COBP represent the disk of the moon, which is turned towards the earth; and let OP be the list of which the semicircle OMP is projected, which suppose to be cut by the diameter BC at right angles; and making LP the radius, take LF equal to the coone of the elongation of the moon from the fund And then upon BC, as the great axis, and LF the Jeffer. axis, describe the semi-ellipse BFC. This ellipse willcut off from the diste of the moon the portion BFCP of the illuminated face, which is visible to us from the earth."

Since in the middle of a total eclipse the moon is ex- place of the actly in the node, if the fun's place be found for that nodes how time, and fix times added to it, if the eclipse is a lunar found. one the fun will give the place of the node, or if the eclipse observed is a solar one, the place of the node and of the fun are the same. From comparing two celipfes together, the mean motion of the nodes will thus he found out. The apogee of the moon may be known from her apparent diameter, as already observed; and by comparing her place when in the apogee at different times, the motion of the apogee itself may also be determined.

These short hints will be sufficient to give a general knowledge of the methods used for the solution of some of the most difficult problems afternomy. As for the proper equations to be added or subtracted, in order to find out the true motion and place of the moon together with the particular methods of constructing tables for calculating eclipses, they are given from Mr Fergulon, in the following fection.

fined.

ing Eclip- Sect. X. Of Eclipses: With Tables for the Calculations; the Method of constructing them; Rules for Calculations, and Directions for the Delineation of Solar and Lunar Eclipfes.

> EVERY planet and fatellite is illuminated by the fun; and casts a shadow towards that point of the heavens which is opposite to the fun. This shadow is nothing but a privation of light in the space hid from the sun

by the opaque body that intercepts his rays. 425 Lelipie de-

When the fun's light is fo intercepted by the moon. that to any place of the earth the fun appears partly or wholly covered, he is faid to undergo an eclipse; though, properly speaking, it is only an eclipse of that part of the earth where the moon's shadow or penumbra falls. When the earth comes between the fun and moon, the moon falls into the earth's shadow; and having no light of her own, the fuffers a real eclipfe from the interception of the fun's rays. When the fun is eclipfed to us, the moon's inhabitants, on the fide next the earth, fee her shadow like a dark spot travelling over the earth, about twice as fast as its equatorial parts move, and the fame way as they move. When the moon is in an eclipse, the fun appears eclipfed to her, total to all those parts on which the earth's shadow falls, and of as long continuance as they are in the shadow.

427 Figure of the earth spherical.

That the earth is spherical (for the hills take off no more from the roundness of the earth; than grains of dust do from the rounduess of a common globe) is evident from the figure of its shadow on the moon; which is always bounded by a circular line, although the earth is inceffantly turning its different fides to the moon, and very feldom shows the same side to her in different ccliples, because they seldom happen at the same hours. Were the earth shaped like a round flat plate, its shadow would only be circular when either of its fides directly faced the moon, and more or less elliptical as the earth happened to be turned more or less obliquely towards the moon when she is eclipsed. The moon's different phases prove her to be round; for as the keeps still the same side towards the earth, if that side were flat, as it appears to be, she would never be visible from the third quarter to the first; and from the first quarter to the third, she would appear as round as when we fay the is full; because, at the end of her first quarter, the fun's light would come as fuddenly on all her fide next the earth, as it does on a flat wall, and go off as abruptly at the end of her third quarrer.

420 Shadows of the earth and moon conical.

Moon's fi-

gure the

faute.

If the earth and fun were equally large, the earth's shadow would be infinitely extended, and all of the fame bulk; and the planet Mars, in either of its nodes and opposite to the fun, would be eclipsed in the earth's shadow. Were the earth larger than the sun, its shadow would increase in bulk the farther it extended, and would eclipfe the great planets Jupiter and Saturn, with all their moons, when they were opposite to the fun. But as Mars, in oppolition, never falls into the earth's shadow, altho' he is not then above 42,000,000 miles from the earth, it is plain that the earth is much less than the fun; for otherwise its shadow could not end in a point at so small a distance. If the sun and moon were equally large, the moon's shadow would go on to the earth with an equal breadth, and cover a por-

tion of the earth's furface more than 2000 miles broad, Of calculaeven if it fell directly against the earth's centre, as feen ting Eclipfrom the moon; and much more if it fell obliquely on the earth: But the moon's fliadow is feldom 150 miles broad at the earth, unless when it falls very obliquely on the earth, in total ecliples of the fun. In annular ecliples, the hoon's real shadow ends in a point at some diffance from the earth. The moon's finall diffance from the earth, and the shortness of her shadow, prove her to be less than the sun. And, as the earth's shadow is large enough to cover the moon, if her diameter were three times as large as it is (which is evident from her long continuance in the fliadow when fine goes through its centre), it is plain that the earth is much bigger than the moon.

Though all opaque bodies, on which the fun fhines, Why there have their fladows, yet fuch is the bulk of the fun, and are in few the diffances of the planets, that the primary planets echiples. can never ecliple one another. A primary can ecliple only its fecondary, or be eclipfed by it: and never but when in opposition or conjunction with the sun. The primary planets are very feldom in these positions, but the fun and moon are fo every month: Whence one may imagine, that thefe two luminaries should be echipfed every month. But there are few echpfes in respect of the number of new and full moons; the reason of

which we shall now explain.

If the moon's orbit were conscident with the plane of the coliptic, in which the earth always moves and the fun appears to move, the moon's fluadow would fall upon the earth at every change, and eclipfe the iun to some parts of the earth. In like manner, the moon would go through the middle of the earth's shadow, and be eclipfed at every full; but with this difference, that she would be totally darkened for above an hour and a half; whereas the fun never was above tour minutes totally eclipfed by the interpolition of the moon. But one half of the moon's orbit is clevated 5! degrees above the coliptic, and the other half as much depreffed below it; confequently, the moon's orbit interfect? the ecliptic in two opposite points called the moon's noder, as has been already taken notice of. When thefe points are in a right line with the centre of the fun at new or full moon, the fun, moon, and earth, are all in a right line; and if the moon be then new, her fliadow falls upon the earth; if full, the earth's shadow falls upon her. When the fun and moon are more than 17 degrees from either of the nodes at the time of conjunction, the moon is then generally too high or too low in her orbit to cast any part of her shadow upon the earth; when the fun is more than 12 degrees from cither of the nodes at the time of full moon, the moon is generally too high or too low in her orbit to go through any part of the earth's shadow: and in both these cases there will be no eclipse. But when the moon is less than 17 degrees from either node at the time of conjunction, her shadow or penumbra falls more or lets upon the earth, as the is more or lefs within this limit. And when the is less than 12 degrees from either node at the time of opposition, the goes through a greater or lefs proportion of the earth's shadow, as she is more or lefs within this limit. Her orbit contains 360 degrees; of which 17, the limit of folar eclipfes on either fide of the nodes, and 12, the limit of lunar ecliples, are but fmall portions: And as the fun commonly passes

Of calcula by the modes but twice in a year, it is no wonder that ting Eclip-we have fo many new and full moons without ecliples.

To illustrate this (fig. 196) let ABCD be the ecliptic, RSTU a circle lying in the fame plane with the ecliptic, and VXYZ the moon's orbit, all thrown into an oblique view, which gives them an elliptical shape to the eye. One half of the moon's orbit, as VWX, is always below the ecliptic, and the other half XYV above it. The points V and X, where the moon's orbit interfects the circle RSTU, which lies even with the ecliptic, are the moon's nodes ; and a right line, as XEV, drawn from one to the other through the earth's centre, is the line of the nodes, which carried almost parallel to itself round the sun in a year.

If the moon moved round the earth in the orbit RSTU, which is coincident with the plane of the ecliptic, her shadow would fall upon the earth every time she is in conjunction with the sun, and at every oppolition she would go through the earth's shadow. Were this the case, the sun would be eclipsed at every change, and the moon at every full, as already mentioned.

But although the moon's shadow N must fall upon the earth at a, when the earth is at E, and the moon in conjunction with the fun at i, because she is then very near one of her nodes; and at her opposition s she must go through the earth's shadow I, because she is then near the other node; yet, in the time that she goes round the earth to the next change, according to the order of the letters XYVW, the earth advances from E to e according to the order of the letters EFGH ; and the line of the nodes VEX, being carried nearly parallel to itself, brings the point f of the moon's orbit in conjunction with the fun at that next change 4 and then the moon being at f, is too high above the ecliptic to cast her shadow on the earth: and as the earth is still moving forward, the moon at her next opposition will be at g, too far below the ecliptic to go through any part of the earth's shadow; for by that time the point g will be at a confiderable distance from the earth as feen from the fun.

When the earth comes to F, the moon in conjunction with the fun Z is not at & in a plane coincident with the ecliptic, but above it at Y in the highest part of her orbit; and then the point b of her shadow O goes far above the earth (as in fig. 2. which is an edge view of fig. 1.) The moon at her next opposition, is not at o (fig. 1.), but at W, where the earth's shadow goes far above her, (as in fig. 2.) In both these cases, the line of the nodes VFX (fig. 1.) is about ninety degrees from the fun, and both luminaries are as far as possible from the limits of the eclipses.

When the earth has gone half round the ecliptic from E to G, the line of the nodes VGX is nearly, if not exactly, directed towards the fun at Z; and then the new moon I casts her shadow P on the earth G; and the full moon p goes through the earth's fandow L; which brings on ecliples again, as when the earth was at E.

When the carth comes to H, the new moon falls not at m in a plane coincident with the ecliptic CD, but at W in her orbit below it; and then her shadow Q (fee fig. 197.) goes far below the earth. At the next full she is not at q (fig. 196.) but at Y in her orbit 57 degrees above on and at her greatest beight above the

ecliptic CD; being then as far as possible at any op-Of calculaposition from the earth's shadow M, as in fig 197.

So, when the earth is at E and G the moon is about her nodes at new and full, and in her greatest north and fouth declination (or latitude as it is generally called) from the ecliptic at her quarters; but when the earth is at F or H, the moon is in her greatest north and fouth declination from the ecliptic at new and full, and in the nodes about her quarters.

The point X, where the moon's orbit crosses the ecliptic, is called the aftending node, because the moon afcends from it above the ecliptic; and the opposite point of interfection V is called the descending node, because the moon descends from it below the ecliptic. When the moon is at Y in the highest point of her orbit, she is in her greatest north latitude, and when she is at W in the lowest point of her orbit, she is in her greatest fouth latitude.

If the line of the nodes, like the earth's axis, was Appear carried parallel to itself round the sun, there would be ance of ejust half a year between the conjunctions of the sun and clipses denodes. But the nodes thift backwards, or contrary from the to the earth's annual motion, 194 deg. every year, and motion of therefore the fame nodes come round the fun 19 days the nodes. fooner every year than on the year before. Confequently, from the time that the elections node X when the earth is at E) palies by the isen in seen from the earth, it is only 173 days (notified from 10) the defeeming node V palies by bins.

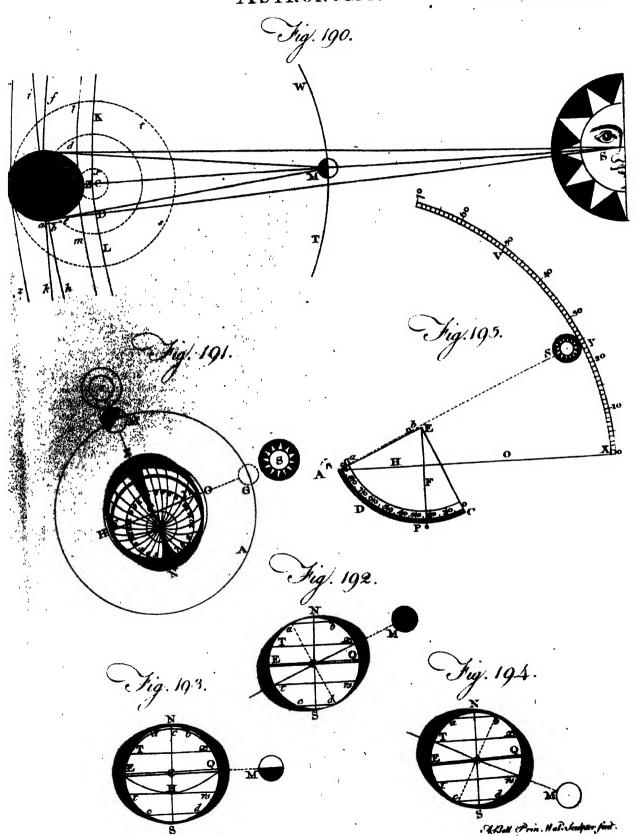

The earth is is only 173 days (notified from 10) the defeeming node V palies by bins.

The defeeming node V palies by bins.

The defeeming node V palies by bins.

And when at any time of the state of through all the figure and degrees of the collecte would years and 225 days; in which time chert would ways be a regular period of ecliples, if any complete number of hunstions were finished without a fraction. But this never happens: for if both the fen and moon should start from a line of conjunction with either of the nodes in any point of the ecliptic, the fun would perform 18 annual revolutions and \$42 degrees over and above, and the moon 230 limations and 85 degrees of the sat, by the time that the node came round to the fame point of the ecliptic again; fo that the fun would then be 138 degrees from the node, and the moon 85 degrees from the fun.

But in 223 mean lunations, after the fun, moon, and nodes, have been once in a line of conjunction, they return so nearly to the fame state again, as that the fame node, which was in conjunction with the fun and moon at the beginning of the first of these lunations will be within 98' 12" of a degree of a line of conjunction with the fun and moon again, when the last of these lunations is completed. And therefore in that time there will be a regular period of eclipfes or return of the same eclipse, for many ages .- In this period, which (was first discovered by the Chaldeans), there are 18 Julian years 11 days 7 hours 43 minutes 20 seconds, when the last day of February in leap-years is four times included; but when it is five times includ-

again.

433 History of

the folar eclipfe in

2764.

Of calcula- ded, the period confifts of only 18 years 10 days 7 hours ting Eclip- 43 minutes 20 seconds. Consequently, if to the mean time of any ecliple, either of the fun or moon, you add 18 Julian years 11 days 7 hours 43 minutes 20 When the seconds, when the last day of February in leap years fame eclipse comes in four times, or a day less when it comes in five times, you will have the mean time of the return of the same eclipse.

> But the falling back of the line of conjunctions or oppositions of the sun and moon 28' 12" with respect to the line of the nodes in every period, will wear it out in process of time; and after that, it will not return again in less than 12,492 years .- These eclipses of the fun, which happen about the afcending node, and begin to come in at the north pole of the earth, will go a little foutherly at each return, till they go quite off the earth at the fouth pole; and those which happen about the descending node, and begin to come in at the fouth pole of the earth, will go a little northerly at each return, till at last they quite leave the earth at the north pole.

> To exemplify this matter, we shall first consider the fun's ecliple (March 21. old ftyle, April 1. new flyle), A. D. 1764, according to its mean revolutions, without equating the times, or the fun's distance from the node; and then according to its true equated

Limes.

This ecliple fell in open space at each return, quite This ecospic fell in open space at each return, quite clear of the shirth eyer since the creation, till A. D. 1399, Jame 130 all flyle, at 12 h. 52 m. 59 fec. poll managion, which the moon's fraction till touched the east that the shorth poles the sun being then 70° 48' will be a the same 28' 12" nearer and nearer than the shirth tile moon's shadow has therefore the shirth and shorth shirth the moon's shadow has therefore the shirth and shirth till have returned 38 times, the sun will be only 24' As" from the assenting code, and the will be only 24' 45" from the ascending node, and the centre of the moon's shadow will fall a little northward of the earth's ocntre.—At the end of the next following period, A. D. 1980, July 28. old flyle, at 18 h. 15 m. 41 fec. p. m. the fun will have receded back 9' 27" from the afoending node, and the moon will have a very small degree of fouthern latitude, which will saufe the centre of her shadow to pais a very small matter fouth of the earth's centre.-After which, in every following period, the fun will be 28' 12" farther back from the alcending node than in the period last before; and the moon's shadow will go still farther and farther fouthward, until September 12. old ftyle, at 23 h. 46 m. 22 fec. p. m. A. D. 2665; when the eclipse will have completed its 77th periodical return, and will go quite off the earth at the fouth pole (the fun being then 27° 55' 22" back from the node), and cannot come in at the north pole, fo as to begin the same course over again, in less than 12,492 years afterwards. And fuch will be the case of every other eclipse of the sun: For, as there is about 18 degrees on each fide of the node within which there is a possibility of eclipses, their whole revolution goes through 36 degrees about that node, which, taken from 360 degrees, leaves remaining 324 degrees for the ecliples to travel in expanfum. And as this 36 degrees is not gone through he less than 77 periods, which takes up 1388 years, Vol. II. Part II.

the remaining 324 degrees cannot be so gone through Of calculain less than 12,492 years. For, as 36 is to 1388, so ting Eclip-18 324 to 12,492.

To illustrate this a little farther, we shall examine fome of the most remarkable circumstances of the re- of the turns of the ecliple which happened July 14. 1748, ecliple in about noon. This eclipse, after traversing the voids 1748. of space from the creation, at last began to enter the Terra Australia Incognita about 88 years after the Conquest, which was the last of King Stephen's reignt every Chaldean period it has crept more northerly, but was still invisible in Britain before the year 1622; when, on the 30th of April, it began to touch the fouth parts of England about two in the afternoon; its central appearance rifing in the American fouth seas, and traverling Peru and the Amazons country, through the Atlantic ocean into Africa, and fetting in the Ethiopian continent, not far from the beginning of the Red

Its next visible period was, after three Chaldean revolutions, in 1676, on the first of June, rising central in the Atlantic ocean, passing us about nine in the morning, with four digits eclipfed on the under limb, and fetting in the gulf of Cochin-Chinz in the East Indies.

It being now near the folftice, this eclipse was vifible the very next return in 1694, in the evening; and in two periods more, which was in 1730, on the 4th. of July, was feen about half eclipfed juit after sunrife, and observed both at Wirtemberg in Germany, and Pekin in China; foon after which it went off.

Eighteen years more afforded us the eclipse which

fell on the 14th of July 1748.

The next viuble return happened on July 25. 1766 in the evening, about 4 digits eclipfed; and, after two periods more, will happen on August 16. 1802, early in the morning, about five digits, the centre coming from the north frozen continent, by the capes of Norway, through Tartary, China, and Japan, to the Ladrone islands, where it goes off.

Again, in 1820, August 26. between one and two, there will be another great eclipse at London, about 10 digits; but, happening so near the equinox, the centre will leave every part of Britain to the west, and enter Germany at Embden, passing by Venice, Naples, Grand Cairo, and let in the gulf of Bassora near that

It will be no more visible till 1874, when sive digits will be obscured (the centre being now about to leave the earth) on September 28. In 1892, the sun will go down eclipsed in London; and again, in 1928, the passage of the centre will be in the expansum, though there will be two digits eclipfed at London, October the 31st of that year, and about the year 2090 the whole penumbra will be wore off; whence no more returns of this eclipse can happen till after a revolution of 10,000 years.

From these remarks on the entire revolution of this Period in ecliple, we may gather, that a thousand years, more or which the less (for there are some irregularities that may protract phenomena or lengthen this period 100 years), complete the whole of an eclipf terrestrial phenomena of any fingle eclipse : and fince 20 pleted. periods of 54 years each, and about 33 days, comprehend the entire extent of their revolution, it is evident, that the times of the returns will pass through a circuit of one year and ten months, every Chaldean period

436 eldom sere than wo ereat cliof. s.m.

he north

nd fouth

oles.

dealculat-being 10 or 11 days later, and of the equable appearig Eclipses, ances, about 32 or 33 days. Thus, though this eclipse happens about the middle of July, no other fublequent eclipse of this period will return till the middle of the fame month again; but wear constantly each period 10 or 11 days forward, and at last appear in winter, but then it begins to cease from affecting us.

Another conclusion from this revolution may be drawn, that there will feldom be any more than two great eclipses of the sun in the interval of this period, his period, and thefe follow fometimes next return, and often at That of 1715 returned again in gierter diflances. 1733 very great; but this present eclipse will not be great till the arrival of 1820, which is a revolution of four Chaldean periods; fo that the irregularities of their circuits mult undergo new computations to assign them exactly.

437 Clipies

Nor do all eclipses come in at the fouth pole: that once in by depends altogether on the polition of the lunar nodes, which will bring in as many from the expansum one way as the other; and fuch eclipses will wear more foutherly by degrees, contrary to what happens in the prefent calc.

> The eclipse, for example, of 1736 in September, had its centre in the expansum, and set about the middle of its obscurity in Britain; it will wear in at the north pole, and in the year 2600, or thereabouts, go off into

> the expansum on the south side of the earth. The eclipses therefore which happened about the

> ereation are little more than half way yet of their ethereal circuit; and will be 4000 years before they enter the earth any more. This grand revolution feems to

have been entirely unknown to the ancients.

It is particularly to be noted, that ecliples which have happened many centuries ago will not be found by our present tables to agree exactly with ancient obated by our servations, by reason of the great anomalies in the lunar motions; which appears an incontestable demonstration of the non-eternity of the universe. For it seems confirmed by undeniable proofs, that the moon now finishes her period in less time than formerly, and will continue, by the centripetal law, to approach nearer and nearer the earth, and to go sooner and sooner round it : nor will the centrifugal power be sufficient to compenfate the different gravitations of fuch an affemblage of bodies as constitute the solar system, which would come to ruin of itself, without some regulation and adjustment of their original motions.

We are credibly informed from the tellimony of the ancients, that there was a total ecliple of the fun predicted by Thales to happen in the fourth year of the 48th Olympiad, either at Sardis or Miletus in Asia, where Thales then refided. That year corresponds to. the 585th year before Christ; when accordingly there happened a very fignal ecliple of the fun, on the 28th of May, answering to the present 10th of that month, central through North America, the fouth parts of France, Italy, &c. as far as Athens, or the isles in the Ægean sea; which is the farthest that even the Caroline tables carry it; and consequently make it invisible to any part of Asia, in the total character; though there are good reasons to believe that it extended to Babylon, and went down central over that city. We are not however to imagine, that it was fet before it

paffed Sardis and the Afiatic towns, where the pre-Of calculat dictor lived; because an invisible eclipse could have ing Eclipse been of no fervice to demonstrate his ability in astronomical science to his countrymen, as it could give no

proof of its reality.

For a further illustration, Thucydides relates, That a folar eclipse happened on a summer's day, in the afternoon, in the first year of the Peloponnesian war, for great, that the stars appeared. Rhodius was victor in the Olympic games the fourth year of the faid war, being also the fourth year of the 87th Olympiad, or the 428th year before Christ. So that the eclipse must have happened in the 431st year before Christ; and by computation it appears, that on the third of August there was a figual cclipse which would have passed over Athens, central about six in the evening, but which our present tables bring no farther than the ancient Syrtes on the African coult, above 400 miles from Athens; which, suffering in that case but nine digits, could by no means exhibit the remarkable darknels recited by this historian : the centre therefore feems to have passed Athens about fix in the evening, and probably might go down about Jerufalem, or near it, contrary to the confirmation of the present tables. Their things are only mentioned by way of caution to the

things are only mentioned by way of crittion to the prefent altronomers, in recomputing abdient ecliples; and they may examine the ecliple of blurias. In fatality to the Athenian feer; that which the mineral feer, that which the mineral feer that which the most usual number is have more than fix. For the modes but once a year, made; in the beginning of the year; the pass by the same mode again a fixed finished; because, as these points means to the points means to the points means to the points means to the present a second to the points means to the points means to the points means to the present a second to the points means to the present the points means the present the finished; because, as these points me backwards every year, the sun will state them 173 days after the other. And given is within 17 degrees of the fun at the time of he moon, the fun will be eclipsed. At the subleque opposition, the moon will be eclipsed in the other node. and come round to the next conjunction again ere the former node be 17 degrees past the fun, and will there-When three eclipses fall. fore ecliple him again, about either node, the like number generally falls. about the opposite; as the sun comes to it in 173 days. afterward; and fix lunations contain but four days. more. Thus, there may be two ecliples of the fun. and one of the moon about each of her nodes. But: when the moon changes in either of the nodes, she cannot be near enough the other node at the next full. to be eclipfed; and in fix lunar months afterward fhe will change near the other node; in these cases, there, can be but two eslipses in a year, and they are both of. the fun.

A longer period than the above-mentioned, for comparing and examining eclipses which happen at long intervals of time, is 557 years 21 days 18 hours 30 minutes 11 feconds; in which time there are 6890 mean lunations; and the fun and node meet again so nearly as to be but it seconds distant; but then it is not the same eclipse that returns, as in the shorter period abovementioned.

Total and annular ecliples.

Ecliples of the fun are more frequent than of the ing Eclip- moon, because the sun's ecliptic limits are greater than the moon's; yet we have more visible eclipses of the moon than of the fun, because eclipses of the moon are Why wore feen from all parts of that hemisphere of the earth ecliples of which is next her, and are equally great to each of the moon those parts: but the sun's eclipses are visible only to than of the that small portion of the hemisphere next hun whereon fun are ob- the moon's shadow falls.

The moon's orbit being elliptical, and the earth in one of its focuses, the is once at her least distance from the earth, and once at her greatest, in every lunation. When the moon changes at her least distance from the earth, and so near the node that her dark shadow falls upon the earth, she appears big enough to cover the whole disk of the sun from that part on which her fhadow falls; and the fun appears totally eclipfed there for fome minutes: but when the moon changes at her greatest distance from the earth, and so near the node that her dark shadow is directed toward the earth, her diameter fubtends a lefs angle than the fun's; and therefore the cannot hide his whole disk from any part of the earth, nor does her shadow reach it at that time; and to the place over which the point of her shadow hange, the eclipse is annular, the fun's edge appearing like a luminous ring all around the body of the moon.

When the change happens within 17 degrees of the node, and the moon at her mean diffence from the earth, the point of her shadow just touches the earth, and the eclipses the fun totally to that small spot

The continue the fun totally to that imail ipot the certain for hading falle, but the darkness is not of a monace's considerate dismeter, when largest, extends the that a when least, only i minute 38 seconds and the greatest colipse of the fun that can happen at my time and place, the total largest continues no longer than whilst the moon is going a minute 38 feconds from the fun in her orbit, which is about 3 minutes and 13 feconds of an

hour.

Extent of

Beginning.

of a folar

eclipfe.

The moon's dark shadow covers only a spot on the the moon's earth's furface about 180 English miles broad, when hadow and the moon's diameter appears largeft, and the fun's leaft; penumbra and the total darkness can extend no farther than the dark shadow covers. Yet the moon's partial shadow or penumbra may then cover a circular space 4000 miles in diameter, within all which the fun is more or less eclipsed, as the places are less or more distant from the centre of the penumbra. When the moon changes exactly in the node, the penumbra is circular on the carth at the middle of the general ecliple; because at that time it falls perpendicularly on the earth's furface; but at every other moment it falls obliquely, and will therefore be elliptical; and the more fo, as the time is longer before or after the middle of the general eclipse; and then much greater portions of the earth's furface are involved in the penumbia.

When the penumbra first touches the earth, the geending, &c. neral eclipse begins; when it leaves the earth, the general eclipse ends: from the beginning to the end the fun appears eclipfed in some part of the earth or other. When the penumbra touches any place, the ecliple hegins at that place, and ends when the penumbra leaves it. When the moon changes in the node, the penumbra goes over the centre of the earth's disk as feen from the moon; and confequently, by describing Of calcula the longest line possibly on the earth, continues the ing Eclip longest upon it; namely, at a mean rate, 5 hours 50 fes, &c minutes; more, if the moon be at her greatest distance from the earth, because she then moves slowest : lesa. if she be at her least distance, because of her quicker

To make several of the above and other phenomena plainer, let S be the fun, E the earth, M the moon, Fig. 198. and AMP the moon's orbit. Draw the right line We from the western side of the sun at W, touching the western side of the moon at c, and the earth at e: draw also the right line V d from the eastern fide of the fun at V, touching the eastern fide of the moon at d, and the earth at e: the dark space ced included between those lines is the moon's shadow, ending in a point at e, where it touches the earth; because in this case the moon is supposed to change at M in the middle between A the apogee, or farthest point of her orbit from the earth, and P the perigee, or 1- arest point to it. For, had the point P been at M, the moon had been nearer the earth; and her dark shadow at e would have covered a space upon it about 180 miles broad, and the fun would have been totally darkened, with some continuance: but had the point A been at M, the moon would have been farther from the earth, and her shadow would have ended in a point a little above e, and therefore the fun would have appeared like a luminous ring all around the moon. Draw the right lines WX dh and VX cg, touching the contrary fides of the fun and moon, and ending on the earth at a and b: draw also the right line SXM, from the centre of the fun's difk, through the moon's centre, to the earth; and suppose the two former lines WX dh and VX cg to revolve on the line SXM as an axis, and their points a and b will describe the hmits of the penumbra TT on the earth's furface, including the large space aba; within which the sun appears more or less eclipsed, as the places are more or less distant from the verge of the penumbra al.

Draw the right line y 12 across the sun's disk, perpendicular to SXM the axis of the penumbra; then divide the line y 12 into twelve equal parts as in the figure, for the twelve digits or equal parts of the fun's diameter; and at equal diffances from the centre of the penumbra at e (on the earth's surface YY) to its edge ab, draw twelve concentric circles, marked with the numeral figures 1 2 3 4, &c. and remember that the moon's motion in her orbit AMP is from west to

eaft, as from s to t. Then,

To an observer on the earth at b, the eastern limb of the moon at d feems to touch the western limb of the fun at W, when the moon is at M; and the fun's eclipse begins at b, appearing as at A, fig. 203. at the left hand: but at the same moment of absolute time, to an observer at a in fig. 198, the western edge of the moon at r leaves the eastern edge of the iun at V, and the eclipse emis, as at the right hand C, fig. 203. At the very fame instant, to all those who live on the circle marked 1 on the earth E, in fig. 198. the moon M cuts off or darkens a twelfth part of the fun S, and eclipfes him one digit, as at 1 in fig. 203: to those who live on the circle marked 2 in fig. 198. the moon cuts off two twelfth parts of the fun, as at 2 in fig. 203: to those on the circle 3, three parts; and so

MCalculat-on to the centre at 12 in fig. 198, where the fun is ing Echp- centrally eclipfed, as at B in the middle of fig. 203.; fee, &c. under which figure there is a scale of hours and minutes, to show at a mean state how long it is from the beginning to the end of a central ecliple of the fun on the parallel of London; and how many digits are eclipfed at any particular time from the beginning at A to the middle at B, or the end at C. Thus, in 16 minutes from the beginning, the fun is two digits eclipsed; in an hour and five minutes, eight digits; and in an hour

and 37 minutes, 12 digits.

By fig. 198. it is plain, that the fun is totally or centrally eclipfed but to a fmall part of the earth at any time, because the dark conical shadow e of the moon M falls but on a small part of the earth; and that the partial eclipse is confined at that time to the space included by the circle a b, of which only one half can be projected in the figure, the other half being supposed to be hid by the convexity of the earth E; and likewise, that no part of the sun is eclipsed to the large space YY of the earth, because the moon is not between the fun and any of that part of the earth; and therefore to all that part the ecliple is invisible. The earth turns eastward on its axis, as from g to b, which is the same way that the moon's shadow moves: but the moon's motion is much swifter in her orbit from s to s: and therefore, although eclipses of the fun are of longer duration on account of the earth's motion on its axis than they would be if that motion was stopped, yet, in four minutes of time at most, the moon's swifter motion carries her dark shadow quite over any place that its centre touches at the time of greatest obscuration. The motion of the shadow on the earth's disk is equal to the moon's motion from the fun, which is about 301 minutes of a degree every hour at a mean rate : but so much of the moon's orbit as equal to 30 t degrees of a great circle on the earth; and therefore the moon's shadow goes 30 t degrees, or 1830 geographical miles on the earth in an hour, or 30 miles in a minute, which is almost four times as swift as the motion of a cannon ball.

As feen from the fun or moon, the earth's axis appears differently inclined every day of the year, on account of keeping its parallelism throughout its annual course. In fig. 205, let EDON be the earth at the two equinoxes and the two folftices, NS its axis, N the north pole, S the fouth pole, AQ the equator, T the tropic of Cancer, t the tropic of Capricorn, and ABC the circumference of the earth's enlightened diffe as feen from the fun or new moon at these times. The earth's axis has the position NES at the vernal equinox, lying towards the right hand, as feen from the fun or new moon; its poles N and S being then in the circumference of the disk; and the equator and all its parallels frem to be straight lines, because their planes pais through the observer's eye looking down upon the earth from the fun or moon directly over E, where the reliptic FG interfects the equator Æ. At the fummer foldlice the earth's axis has the position NDS; and part of the ecliptic FG, in which the moon is then new, touches the tropic of Cancer T at D. The north polity at that time inclining 23 degrees towards the lung falls fo many degrees within the earth's enlightened con, because the fun is then vertical to D 231 degrees north of the equator ÆQ; and the equator,

with all its parallels from elliptic curves bending down. Of Calcula ward, or towards the fouth pole, as feen from the fun; ing Beligwhich pole, together with 23 degrees all round it, is hid behind the disk in the dark hemisphere of the earth. At the autumnal equinox, the earth's axis has the position NOS, lying to the left hand as seen from the fun or new moon, which are then vertical to O, where the ecliptic cuts the equator ÆQ. Both poles now he in the circumference of the diffe, the north pole just going to disappear behind it, and the south pole just entering into it; and the equator with all its parallels feem to be straight lines, because their planes pals through the observer's eye, as seen from the sun, and very nearly to as feen from the moon. At the winter solftice, the earth's axis has the position NNS when its fouth pole S inchming 23 th degrees towards the fun, falls 23 degrees within the enlightened difk, as feen from the fun or new moon, which are then vertical to the tropic of Capricorn t, 234 degrees fouth of the equator EQ; and the equator, with all its parallels, feem elliptic curves bending, upward; the north pole being as far hid behind the disk in the dark hemisphere as the south pole is come into the light. The nearer that any time of the year, is to the equipoxes or folltices, the more it partakes of the phonomera, re-

or iolitices, the more it partakes of the phenomena to lating to them.

Thus it appears, that from the rerus periods to autumnal, the nouth pule is entire to the feet and all its parallels attended to the from the fun, more at left partallels attended to to, or farther from the parallels attended to, or farther from the same parallels which happens from the same parallels which happens from the same parallels wince the reader, that the careful vince the reader, that the careful winter folflice; and fidewife to the moxes; but towards the right hand, as the fun at the versal equinox; and towards the figure at the autumnal. From the winter to the funners at the autumnal. From the winter to the famous all flice, the earth's axis inclines more or left to the hand, as feen from the fun; and the contrary from the

fummer to the winter folflice. The different politions of the carth's axis. . se feen B from the fun at different times of the year, affect foleraffected by colliples greatly with regard to particular places; yes, the political fo far as would make central ecliples which fall at one earth's axis. time of the year invisible if they fell at another, even though the moon should always change in the nodes. and at the same hour of the day; of which indefinitely various affections, we shall only give examples for the times of the equinoxes and folflices.

In the same diagram, let FG be part of the ecliptic, and IK, ik, ik, ik, part of the moon's orbit; both seen edgewise, and therefore projected into right lines; and let the intersections NODE be one and the fame node at the above times, when the earth has the forementioned different positions; and let the spaces included by the circles Pppp be the penumbra at these times, as its centre is passing over the centre of the earth's disk. At the winter solftice, when the earth's axis has the polition NNS, the centre of the penumbra P touches the tropic of Capricorn in N at the middle of the general eclipse; but no part of the penumbra touches the tropic of Cancer T. At the fummer.

Of calcula furniter lofflice, when the earth's axis has the polition ting Ecap MDS (i D & being then part of the moon's orbit for set. whose node is at D), the penumbra p has its centre at D, on the tropic of Cancer T, at the middle of the general ecliple, and then no part of it touches the tropic of Capricorn t. At the autumnal equinox, the earth's axis has the polition NOS (i O & being then part of the moon's orbit), and the penumbra equally includes part of both tropics T and t, at the middle of the general eclipse: at the vernal equinox it does the fame, because the earth's axis has the position NES; but, in the former of these two fast cases, the penumbra enters the earth at A, north of the tropic of Cancer T, and leaves it at m fouth of the tropic of Capricorn 1; having gone over the earth obliquely fouthward, as its centre described the line AOm: whereas, in the latter case, the penumbra touches the earth at #, fourh of the equator ÆQ, and describing the line nEq

north of the equator.

In all these circumstances the moon has been supposed to change at moon in her descending node: Had she changed in her ascending node, the phenomena would have been as various the contrary way, with respect to the parameter's going northward or southward over the care. But because the moon changes at all hours, as after him because the moon changes at all distances from the both at different times as it happens the variables which the phases of eclipses are almost an interesting the variables of eclips are almost an interesting the variables of the phases of eclips are almost an interesting the variables of the phases are finished on the called the light of the party with respect to the pennances when eclipses the moon changes to degrees front of her decembers the moon changes to degrees front of her decembers the moon changes to degrees front of her decembers the instrument.

(fimilar to the former line AOm in open space), goes

obliquely northward over the earth, and leaves it at q,.

for solling solle, the penumbra P18 just touches the southern past of the earth's disk, near the north pole We said as feen from that place, the moon appears to souch the fun, but hides no part of him from light. Had the change been as far fhort of the afcending mode, the penumbra would have touched the fouthern part of the disk near the fouth pole S. When the moon changes is degrees thort of the defcending node, more than a third part of the penumbra P12 falls on the A northern parts of the earth at the middle of the general ecliple: Had she changed as far past the same node, as much of the other fide of the penumbra about P would have fallen on the fouthern part of the earth; all the reft in the expansum, or open space. When the moon changes 6 degrees from the node, almost the whole penumbra P6 falls on the earth at the middle of the general eclipse. And lastly, When the moon changes in the node at N, the penumbra PN takes the longest course possible on the earth's disk; its centre falling on the middle thereof, at the middle of the general eclipse. The farther the moon changes from either node, within 17 degrees of it, the shorter is the penumbra's continuance on the earth, because it goes over a less portion of the disk, as is evident by the

Duration of The nearer that the penumbra's centre is to the celipfes in equator at the middle of the general eclipfe, the longer different is the duration of the eclipfe at all those places where parts of the it is central; because, the nearer that any place is to earth.

the equator, the greater is the circle it describes by Of calcalante the earth's motion on its axis: and so, the place moveting Eclipting quicker, keeps longer in the penumbra, whose motion is the same way with that of the place, though safter, as has been already mentioned. Thus (see the earth at D and the penumbra at 12) whilst the point b in the polar circle abcd is carried from btoc by the earth's diarnal motion, the point d on the tropic of Cancer T is carried a much greater length from d to D; and therefore, if the penumbra's centre goes one time over c and another time over D, the penumbra will be longer in passing over the moving place d than it was in passing over the moving place d. Consequently, central eclipses about the poles are of the shortest duration; and about the equator, of the longest.

In the middle of fummer, the whole frigid zone, included by the polar circle abed, is enlightened: and if it then happens that the penumbra's centre goes over the north pole, the sun will be eclipsed much the same number of digits at a as at c; but whilst the penumbra moves eastward over c, it moves eastward over a; because, with respect to the penumbra, the motions of a and c are contrary: for c moves the same way with the penumbra towards d, but a moves the contrary way towards b; and therefore the eclipse will be of longer duration at c than at a. At a the eclipse begins on the sun's eastern limb, but at c on his western: at all places lying without the polar circles, the fun's cclipfes begin on his western limb, or near it, and end on or near his eastern. At those places where the penumbra touches the earth, the eclipse begins with the rifing fun, on the top of his western or uppermost edge: and at those places where the penumbra leaves the earth, the eclipse ends with the setting sun, on the top of his eastern edge, which is then the uppermost, just at its disappearing in the horizon.

If the moon were furrounded by an atmosphere of any considerable density, it would seem to touch the sun a little before the moon made her appulse to his edge, and we should see a little faintness on that edge before it were eclipsed by the moon: but as no such faintness has been observed, it seems plain, that the moon has no such atmosphere as that of the earth. The faint ring of light surrounding the sun in total celipses, called by Cassini la chevelure du soleil, is said to be the atmosphere of the sun; because it has been observed to move equally with the sun, not with the moon. See N° 147.

Having been to prolix concerning eclipses of the sun, Lunar we shall drop that subject at present, and proceed to the eclipses exdectrine of lunar eclipses; which being more simple, plained, may be explained in less time.

That the moon can never be eclipfed but at the time of her being full, and the reason why she is not eclipsed at every full, has been shown already. In sig. 198, let S be the sun, E the earth, RR the earth's shadow, and B the moon in opposition to the sun: In this situation the earth intercepts the sun's light in its way to the moon; and when the moon touches the earth's shadow at v, she begins to be eclipsed on her eastern limb s, and continues eclipsed until her western limb s leaves the shadow at w: at B she is in the middle of the shadow, and consequently in the middle of the eclipse.

The moon, when totally eclipfed, is not invisible if

She

Why the eclipfed.

Of calculat- the be above the horizon and the fky he clear; but aping Eclip- pears generally of a dusky colour, like tarnished copper, which some have thought to be the moon's native light. But the true cause of her being visible is the scattered beams of the sun, bent upon the earth's shamoon is vi-dow by going through the atmosphere; which, being sib'e when more or less dense near the earth than at confiderable heights above it, refracts or bends the fun's rays more inward, the nearer they are passing by the earth's furface, than those rays which go through higher parts of the atmosphere, where it is less dense according to its height, until it be so thin or rare as to lose its refractive power. Let the circle f, g, h, i, concentric to the earth, include the atmosphere whose refractive power vanishes at the heights f and i; so that the rays Wfw and Viv go on ftraight without fuffering the leaft refraction: but all those rays which enter the atmosphere between f and k, and between i and l, on opposite sides of the earth, are gradually more bent inward as they go through a greater portion of the atmosphere, until the rays Wk and VI touching the earth at m and n, are bent so much as to meet at q, a little short of the moon; and therefore the dark shadow of the earth is contained in the space moqpn, where none of the sun's rays can enter; all the rest R, R, being mixed by the scattered rays which are refracted as above, is in some measure enlightened by them; and fome of those rays falling on the moon, give her the colour of tarnished copper or of iron almost red hot. So that if the earth had no atmosphere, the moon would be as invisible in total eclipses as the is when new. If the moon were fo near the earth as to go into its dark shadow, suppose about po, she would be invisible during her stay in it; but visible before and after in the fainter shadow RR.

> When the moon goes through the centre of the earth's shadow she is directly opposite to the sun; yet the moon has been often feen totally eclipfed in the horizon when the fun was also visible in the opposite part of it; for the horizontal refraction being almost 34 minutes of a degree, and the diameter of the fun and moon being each at a mean flate but 32 minutes, the refraction causes both luminaries to appear above the horizon when they are really below it.

> When the moon is full at 11 degrees from either of her nodes, the just touches the earth's shadow, but enters not into it. In fig. 204. let GH be the ecliptic, ef the moon's orbit where the is 12 degrees from the node at her full, cd her orbit where she is 6 degrees from the node, a b her orbit where she is full in the node, AB the earth's shadow, and M the moon. When the moon describes the line ef, she just touches the shadow, but does not enter into it; when she deferibes the line cd, the is totally, though not centrally, immerfed in the shadow; and when she describes the line a b, the passes by the node at M in the centre of the shadow, and takes the longest line possible, which is a diameter, through it : and fuch an eclipfe being both total and central, is of the longest duration, namely, 3 hours 57 minutes 6 feconds from the beginning to the end, if the moon be at her greatest distance from the earth; and 3 hours 37 minutes 26 feconds, if she be at her least distance. The reason of this difference is, that when the moon is farthest from the earth, she moves flowest; and when nearest to it, quickest.

The moon's diameter, as well as the fun's, is suppos-

fed to be divided into 12 equal parts, called digits; and Of calcula fo many of these parts as are darkened by the earth's ing Echp shadow, so many digits is the moon eclipsed. All that fes, &c. the moon is eclipfed above 12 digits, shows how far the shadow of the earth is over the body of the moon, on that edge to which she is nearest at the middle of the

It is difficult to observe exactly either the beginning Lunar or ending of a lunar ecliple, even with a good telescope, ecliples because the earth's shadow is so faint and ill-defined difficultly about the edges, that when the moon is either just observed. touching or leaving it, the obscuration of her limb is scarce sensible; and therefore the nicest observers can hardly be certain to four or five seconds of time. But both the beginning and ending of folar eclipfes are vifibly instantaneous; for the moment that the edge of the moon's disk touches the fun's his roundness feems a little broke on that part; and the moment she leaves it, he appears perfectly round again.

In aftronomy, ecliples of the moon are of great use Eclipses for ascertaining the periods of her motions; especially useful in de fuch ecliples as are observed to be alike in all her cir-termining cumstances, and have long intervals of time between longitudes them. In geography, the longitudes of places are ac. found by ecliples; but for this purpole ecliples of the moon are more useful than those of the fun, because they are more frequently viable, and the fame lunar eclipfe is of equal largeness and distraction at all places where it is seen. In chronology, half folia and lunar eclipses serve to determine exactly the time of any past event: for there are so many past and the covery eclipse, with respect to its quantities of the places where it is visible (if of the lun), that the last of the day or night, that it is impossible them all the course of many times a line in all the all circumstances.

From the above explanation of the doctries of the periods fes, it is evident that the darkness of one Savious for the factor on which the passor was eaten by the Jews, on which the passor was eaten by the Jews, on which the passor in because it is the passor in the pa day it was impossible that the moon's shadow could fan pernatural on the earth; for the Jews kept the passover at the time of full moon; nor does the darkness in total eclipfes of the fun last above four minutes in any place? whereas the darkness at the crucifixion lafted three hours, Matth. xxviii. 15. and overspread at least all the land of Judea.

The theory of ecliples being now, we hope, pretty Confirucplainly laid down, the construction of tables for their tion of calculation will be understood from the following con-tables for fiderations.

The motions of the fun and moon are observed to echipses. be continually accelerated from the apogee to the perigee, and as gradually retarded from the perigee to the apogee; being flowest of all when the mean anomaly is nothing, and swiftest of all when it is fix

When the luminary is in its apogee or perigee, its place is the same as it would be if its motion were equable in all parts of its orbit. The supposed equable motions are called mean; the unequable are justly called the true.

The mean place of the fun or moon is always forwarder than the true place, whilft the luminary is moving from its apogee to its perigree: and the true

calculating

place

If calculate place is always forwarder than the mean, whilft the ing Eclip- luminary is moving from its perigee to its apogee. In fes, &c. the former case, the anomaly is always less than fix

figns, and in the latter case, more.

It has been found, by a long series of observations, that the fun goes through the celiptic, from the vernal equinox to the fame equinox again, in 365 days 5 hours 48 minutes 55 feconds; from the first slar of Aries to the same star again, in 365 days 6 hours 9 minutes 24 feconds; and from his apogee to the same again, in 365 days 6 hours 14 minutes o seconds .-The first of these is called the folar year; the second the fidereal year; and the third the anomalistic year. So that the folar year is 20 minutes 29 feconds shorter than the fidereal; and the fidereal year is four minutes 36 feconds shorter than the anomalistic. Hence it appears, that the equinoctial point, or interlection of the ecliptic and equator at the beginning of Aries, goes backward with respect to the fixed stars, and that the fun's apogee goes forward.

It is also observed, that the moon goes through her orbit, from any given fixed ftar to the same star again, in 27 days 7 hours 43 minutes 4 feconds at a mean rate; from her apogee to her apogee again, in 27 days 13 hours 18 minutes 43 feconds; and from the fun to the fun again, in 20 days 12 hours 44 minutes 310 feconds. This shows that the moon's apogee moves forward in the ecliptic, and that at a much quicker rate than the fun's apogee does; fince the moon is 5 hours 55 minutes 30 feconds longer in revolving from her apogee to her apogee again, than from any star to the same

far again.

The moon's orbit croffes the ecliptic in two oppofire points, which are called her Nodes: and it is obferved, that the revolves fooner from any node to the node again, than from any flar to the flar again, by 2 hours 38 minutes 27 feconds; which shows, that her nodes move backward, or contrary to the order of figns.

in the ecliptic.

The time in which the moon revolves from the fun. to the fun again (or from change to change) is called Lunation : which, according to Dr Pound's mean measures, would always confist of 29 days 12 hours. 44 minutes 3 seconds 2 thirds 58 fourths, if the motions of the fun and moon were always equable. Hence 1.2 mean lunations contain 354 days 8 hours 48 minutes 36 feconds 35 thirds 40 fourths, which is 10 days 21 hours 11 minutes 23 feconds 24 thirds 20 fourths less than the length of a common Julian year, consisting of 365 days 6 hours; and 13 mean lunations contain 383 days 21 hours 32 minutes 39 feconds 38 thirds 38 fourths, which exceeds the length of a common Julian year, by 18 days 15 hours 32 minutes 39 feconds 38 thirds 38 fourths.

The mean time of new moon being found for any given year and month, as suppose for March 1700, old ftyle, if this mean new moon falls later than the 11th day of March, then 12 mean lunations added to the time of this mean new moon will give the time of the mean new moon in March 1701, after having thrown off 365 days. But when the mean new moon happens to be before the 11th of March, we must add 13 mean lunations, in order to have the time of mean new moon in March the year following; always taking

care to subtract 365 days in common years, and 366 Of calculatdays in leap years, from the fum of this addition.

Thus, A. D. 1700, old style, the time of mean ses, &c. new moon in March was the 8th day, at 16 hours 11 minutes 25 feconds after the noon of that day (viz. at 11 minutes 25 feconds past four in the morning of the 9th day), according to common reckoning. To this we must add 13 mean lunations, or 383 days 21 hours 32 minutes 39 feconds 38 thirds 38 fourths, and the fum will be 392 days 13 hours 44 minutes 4 feconds 38 thirds 38 fourths: from which subtract 365 days, because the year 1701 is a common year, and there will remain 27 days 13 hours 44 minutes 4 feconds 38 thirds 38 fourths for the time of mean new moon in March, A. D. 1701.

Carrying on this addition and fubtraction till A. D. 1703, we find the time of mean new moon in March that year to be on the 6th day, at 7 hours 21 minutes 17 feconds 49 thirds 46 fourths past noon; to which add 13 mean lunations, and the fum will be 390 days 4 hours 53 minutes 57 feconds 28 thirds 20 fourtlis; from which subtract 366 days, because the year 1704 is a leap year, and there will remain 24 days 4 hours 53 minutes 57 feconds 28 thirds 20 fourths, for the time of mean new moon in March, A. D. 1704.

In this manner was the first of the following tables constructed to seconds, thirds, and fourths; and then wrote out to the nearest seconds. The reason why we chofe to begin the year with March was to avoid the inconvenience of adding a day to the tabular time in leap years after February, or fubtracting a day therefrom in January and February in those years; to which all tables of this kind are subject, which begin the year with January, in calculating the times of new or full moons.

The mean anomalies of the fun and moon, and the fun's mean motion from the ascending node of the moon's orbit, are fet down in Table III. from 1 to 13 mean lunations. These numbers, for 13 lunations, being added to the radical anomalies of the fun and moon, and to the fun's mean diffauce from the afcending node, at the time of mean new moon in March 1700 (Table I.), will give their mean a tomalies, and the fun's mean distance from the node, at the time of mean new moon in March 1701 and being added for 12 lunations to those for 1701, give them for the time of mean new moon in March 1702. And fo on as far as you please to continue the table (which is here carried on to the year 1800), always throwing off 12 figns when their fum exceeds 12, and fetting down the remainder as the proper quantity.

If the numbers belonging to A. D. 1700 (in Table I.) be subtracted from those belonging to 1800, we shall have their whole differences in 100 complete Julian years; which accordingly we find to be 4 days 8 hours 10 minutes 52 feconds 15 thirds 40 fourths, with respect to the time of mean new moon. These heing added together 60 times (always taking care to throw off a whole lunation when the days exceed 291) make up 60 centuries, or 6000 years, as in Table VI. which was carried on to feconds, thirds, and fourths; and then wrote out to the nearest seconds. In the fame manner were the respective anomalies and the fun's distance from the node found, for these cen...

15

Of calcula-turial years, and then (for want of room) wrote out onting Eclip- ly to the nearest minutes, which is sufficient in whole centuries. By means of thefe two tables, we may find the time of any mean new moon in March, together with the anomalies of the fun and moon, and the fun's distance from the node at these times, within the limits of 6000 years either before or after any given year in the 18th century; and the mean time of any new or full moon in any given month after March, by means of the third and fourth tables, within the fame limits, as shown in the precepts for calculation.

Thus it would be a very eafy matter to calculate the time of any new or full moon, if the fun and moon moved equably in all parts of their orbits. But we have already shown, that their places are never the same as they would be by equable motions, except when they are in apogee or perigee; which is, when their mean anomalies are either nothing or fix figns; and that their mean places are always forwarder than their true places, whilft the anomaly is less than fix figns; and their true places are forwarder than the mean,

whilft the anomaly is more.

Hence it is evident, that whilst the sun's anomaly is lefs than fix figus, the moon will overtake him, or be opposite to him, sooner than she could if his motion were equable; and later whilst his anomaly is more than six signs. The greatest difference that can posfibly happen between the mean and true time of new or full moon, on account of the inequality of the fun's motion, is 3 hours 48 minutes 28 feconds: and that is, when the fun's anomaly is either 3 figns 1 degree, or 8 signs 29 degrees; sooner in the sirst case, and later in the last .- In all other figns and degrees of anomaly, the difference is gradually less, and vanishes when the anomaly is either nothing or fix figns.

The fun is in his apogee on the 30th of June, and in his perigee on the 30th of December, in the prefent age: fo that he is nearer the earth in our winter than in our fummer.-The proportional difference of distance, deduced from the difference of the fun's apparent diameter at these times, is as 983 to 1017.

The moon's orbit is dilated in winter, and contracted in summer; therefore the lunations are longer in winter than in summer. The greatest difference is found to be 22 minutes 29 seconds; the lunations increafing gradually in length whilst the fun is moving from his apogee to his perigee, and decreasing in length whilft he is moving from his perigee to his apogee.—On this account, the moon will be later every time in coming to her conjunction with the fun, or being in opposition to him, from December till June, and sooner from June till December, than if her orbit had continued of the fame fize all the year round.

As both these differences depend on the sun's anomaly, they may be fitly put together into one table, and called The annual or first equation of the mean to the true syzygy, (see Table VII.) This equational disference is to be subtracted from the time of the mean fyzygy when the fun's anomaly is lefs than fix figns, and added when the anamoly is more.—At the greatest it is 4 hours 10 minutes 57 seconds, viz 3 hours 48 minutes 28 feconds, on account of the fun's unequal motion, and 22 minutes 29 feconds, on account of the dilatation of the moon's orbit.

This compound equation would be fufficient for re-

ducing the mean time of new or full moon to the true Of calcultime thereof, if the moon's orbit were of a circular ting Eclipform, and her motion quite equable in it. But the moon's orbit is more elliptical than the fun's, and her motion in it so much the more unequal. The difference is so great, that she is sometimes in conjunction with the fun, or in opposition to him, sooner by 9 hours 47 minutes 54 seconds, than she would be if her motion were equable; and at other times as much later. The former happens when her mean anomaly is 9 figns 4 degrees, and the latter when it is 2 figns 26 degrees. See Table IX.

At different distances of the sun from the moon's apogee, the figure of the moon's orbit becomes different. It is longest of all, or most eccentric, when the fun is in the same signand degree either with the moon's apogee or perigee; shortest of all, or least eccentric, when the fun's distance from the moon's apogee is either three figns or nine figns; and at a mean state when the distance is either I fign 15 degrees, 4 figns 15 degrees, 7 figns 15 degrees, or 10 figns 15 degrees. When the moon's orbit is at its greatest eccentricity, her apogeal distance from the earth's centre is to her perigeal diffance therefrom, as 1067 is to 933; when least eccentric, as 1043 is to 957; and when at the mean state; as 1055 is to 945.

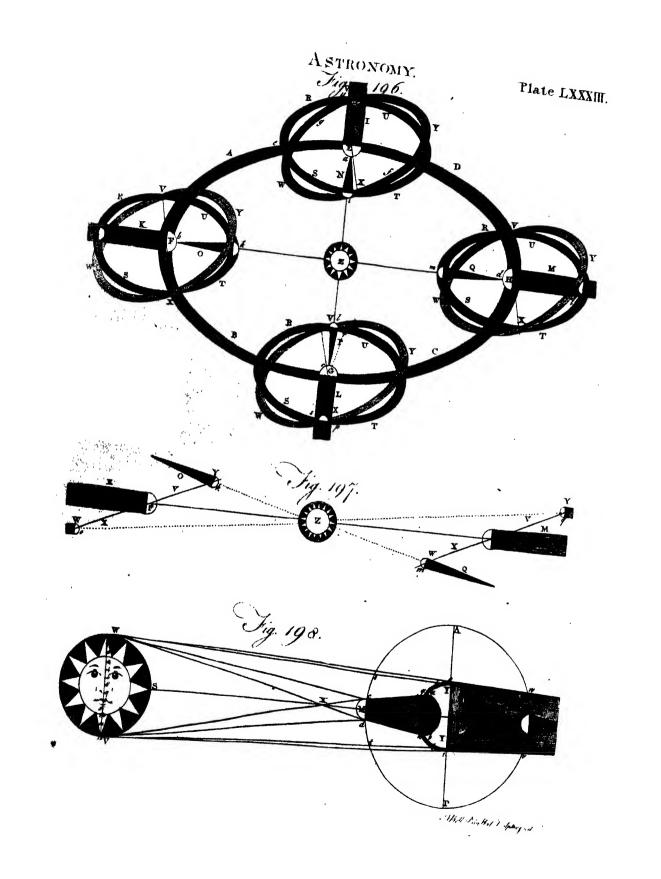

But the fun's distance from the moon's apoges is equal to the quantity of the moon's mean anomaly at the time of new moon, and by the addition of 6 figure it becomes equal in quantity to the moon's more accmaly at the time of full moon. Therefore, a table may be constructed to as to answer to all the mirrous inequalities depending on the different accomments the moon's orbit, in the fyzygies, and the The cond equation of the mean to the true from the law be IX.): and the moon's anomaly, when necessarily Table VIII. may be made the proper significant for taking out this fecond equation of time; which must be added to the former equated time, when the mooning anomaly is lefs than fix figns, and fubtracted when the anomaly is more.

There are several other inequalities in the moon's motion, which fometimes bring on the true fyzygy o little sooner, and at other times keep it back, a little later, than it would otherwise be; but they are so small that they may be all omitted except two; the former of which (see Table X.) depends on the difference between the anomalies of the fun and moon in the fyzygies, and the latter (fee Table XI.) depends on the fun's distance from the moon's nodes at these times .- The greatest difference arising from the former is 4 minutes 58 feconds; and from the latter, 1 minute 34 feconds.

The tables here inferted being calculated by Mr Ferguson according to the methods already given, he gives the following directions for their use.

To calculate the true Time of New or Full Moon.

PRECEPT I. If the required time be within the H. Direction mits of the 18th century, write out the mean time of for the u new moon in March, for the proposed year, from Table of those I. in the old flyle, or from Table II. in the new; together with the mean anomalies of the fun and moon, and the fun's mean diffance from the moon's afcending node. If you want the time of full moon in March, add the half lunation at the foot of Table III. with

of Calcula- its anomalies, &c. to the former numbers, if the new eing Echpmoon falls before the 15th of March; but if it falls after, &c. ter, fubtract the half lunation, with the anomalies, &c. belonging to it, from the former numbers, and write down the respective sums or remainders.

II. In these additions or subtractions, observe, that 60 seconds make a minute, 60 minutes make a degree, 30 degrees make a sign, and 12 signs make a circle. When you exceed 12 signs in addition, reject 12, and set down the remainder. When the number of signs to be subtracted is greater than the number you subtract from, add 12 signs to the lesser number, and then you will have a remainder to set down. In the tables signs are marked thus s, degrees thus ninutes thus, and seconds thus.

III. When the required new or full moon is in any given month after March, write out as many lunations with their anomalies, and the fun's distance from the node from Table III. as the given month is after March, fetting them in order below the numbers taken out for March.

IV. Add all these together, and they will give the mean time of the required new or full moon, with the mean anomalies and sun's mean distance from the ascending node, which are the arguments for finding the proper equations.

V. With the number of days added together, enter Table IV. under the given month; and against that number was like the day of mean new or full moon in the last hand adding, which set before the hours, minutes, and lectures already found.

but (usife will fometimes happen) if the faid number of days fall fact of any in the column under the given triggith, and one impation and its anomalies, &c. from Table MIL) to the forefaid fums, and then you will have new fum of days wherewith to enter Pable M. under the given month, where you are fure to find it the second time, if the first falls short.

VI. With the figns and degrees of the fun's anomaly, emer Table VII. and therewith take out the annual or first equation for reducing the mean syzygy to the true; taking care to make proportions in the table for the odd minutes and seconds of anomaly, as the table gives the equation only to whole degrees.

Observe, in this and every other case of sinding equations, that if the signs are at the head of the table, their degrees are at the left hand, and are reckened downwards; but if the signs are at the foot of the table, their degrees are at the right hand, and are counted upward; the equation being in the body of the table,

under or over the figns, in a collateral line with the Of Calculadegrees. The titles Add or Subtrast at the head or ting Palipfoot of the tables where the figns are found, show whether the equation is to be added to the mean time of new or full moon, or to be subtracted from it. In this table, the equation is to be subtracted, if the figns of the sum anomaly are found at the head of the table; but it is to be added, if the signs are at the foot.

VII. With the figns and degrees of the fun's mean anomaly, enter Table VIII. and take out the equation of the moon's mean anomaly; fubtract this equation from her mean anomaly, if the figns of the fun's anomaly be at the head of the table, but add it if they are at the foot; the refult will be the moon's equated anomaly, with which enter Table IX. and take out the fecond equation for reducing the mean to the true time of new or full moon; adding this equation, if the figns of the moon's anomaly are at the head of the table, but fubtracting it if they are at the foot; and the refult will give you the mean time of the required new or full moon twice equated, which will be fufficiently near for common almanacks. - But when you want to calculate an eclipfe, the following equations must be used: thus,

VIII. Subtract the moon's equated anomaly from the fun's mean anomaly, and with the remainder in figure and degrees enter Table X. and take out the third equation, applying it to the former equated time, as the titles Add or Subtract do direct.

IX. With the fun's mean diffance from the afcending node enter Table XI. and take out the equation answering to that argument, adding it to, or subtracting it from, the forner equated time, as the titles direct, and the result will give the time of new or full moon, agreeing with well regulated clocks or watches very near the truth. But to make it agree with the solar, or apparent time, you must apply the equation of natural days, taken from an equation table, as it is leap year, or the soft, second, or third after. This, however, unless in very nice calculations, needs not be regarded, as the difference between time and apparent time is never very considerable.

The method of calculating the time of any new or full moon without the limits of the 18th century will be shown further on. And a few examples compared with the precepts will make the whole work plan.

N. B. The tables begin the day at noon, and reckon forwards from thence to the noon following.—Thus, March the 31st at 23 ho. 30 min. 25 sec. of tabular time is April 1st (in common reckoning) at 30 min. 25 sec. after 10 o'clock in the morning.

Of Calcula- To calculate the true time of New or Full Moon in any given year and month after the 18th century.

PRECEPT I. Find a year of the same number in the 18th century with that of the year proposed, and take out the mean time and anomalies, &c. of new moon in March, old flyle, for that year, in Table I.

II. Take fo many years from Table VI. as when added to the above-mentioned year in the 18th century

will answer to the given year in which the new or full of Calculamoon is required; and take out the first new moon, ting Eclipfes, &c. with its anomalies for these complete centuries.

III. Add all these together, and then work in all respects as above shown, only remember to subtract a lunation and its anomalies, when the above-faid addition carries the new moon beyond the 31st of March; as in the following example.

EXAMPLE VII.

Required the true time of New Moon in July, Old Style, A. D. 2180? Tour centuries (or 400 years) added to A. D. 1780, make 2180.

In keeping by the old style, we are always fure to be right, by adding or subtracting whole hundreds of years to or from any given year in the 18th century. But in the new style we may be very apt to make miftakes, on account of the leap year's not coming in regularly every fourth year: and therefore, when we go without the limits of the 18th century, we had best keep to the old style, and at the end of the calculation reduce the time to the new. Thus, in the 22d century there will be fourteen days difference between the flyles; and therefore the true time of new moon in this last example being reduced to the new style will be the 22d of July, at 22 minutes 55 feconds past fix in the evening.

True time, July,

To calculate the true place of the Sun for any given

Moment of Time.

PRECEPT I. In Table XII. find the next leffer year in number to that in which the fun's place is fought, and write out his mean longitude and anomaly anfwering thereto: to which add his mean motion and

anomaly for the complete relidue of years, months, days, hours, minutes, and icconds, down to the given time. and this will be the fun's mean place and anomaly at that time, in the old ftyle, provided the faid time be in any year after the Christian era. See the first following example.

II. Enter Table XIII. with the sun's mean anomaly, and making proportions for the odd minutes and feconds thereof, take out the equation of the fun's centre: which, being applied to his mean place as the title Add or Subtrati directs, will give his true place or longitude from the vernal equinox, at the time for which it was required.

III. To calculate the fun's place for any time in a given year before the Christian era, take out his meau longitude and anomaly for the first year thereof. and from these numbers subtract the mean motions and anomalies for the complete hundreds or thoufands next above the given year; and to the remainders. add those for the refidue of years, months, &c. and then work in all respects as above. See the second example following.

fee, &c.

Of Calculating Eclipation, &c.

EXAMPLE I.

Required the Sun's true place, March 20th, Old Style, 1764, at 22 hours 30 minutes 25 seconds pust noon?

In common reckoning, March 21st, at 10 hours 30 minutes 25 seconds in the forenoon.

EXAMPLE II.

Required the Sun's true place, October 23d, Old Style, at 16 hours 57 minutes past noon, in the 408th year before the year of Christ 1; which was the 407th before the year of his birth, and the year of the Julian period 706.

So that in the meridian of London, the sun was then just entering the sign . Libra, and consequently was upon the point of the autumnal equinox.

If to the above time of the autumnal equinox at London, we add 2 hours 25 minutes 41 feconds for the longitude of Babylon, we shall have for the time of the same equinox, at that place, October 23d, at 19 hours 22 minutes 41 feconds; which, in the common way of reckoning, is October 24th, at 22 minutes 41 feconds past seven in the morning.

And it appears by Example VI. that in the same year the true time of full moon at Babylon was October 23d, at 42 minutes 46 seconds after six in the morning f so that the autumnal equinox was on the day next the day of full moon.—The dominical letter for

that year was G, and confequently the 24th of October was on a Wednefday.

To find the Sun's distance from the moon's ascending node, at the time of any given new or full moon: and consequently, to know whether there is an eclipse at that time or not.

The fun's distance from the moon's alcending node is the argument for finding the moon's fourth equation in the fyzygies; and therefore it is taken into all the foregoing examples in finding the times thereof. Thus, at the time of mean new moon in April 1764, the fun's mean distance from the ascending node is 0° 5° 35' 2". See Example I. p. 562.

461

463

Of Calcula- The descending node is opposite to the ascending ung Echp one, and they are just fix figus distant from each see, &c. other.

When the sun is within 17 degrees of either of the nodes at the time of new moon, he will be colipsed at that time; and when he is within 12 degrees of either of the nodes at the time of sull moon, the moon will be then celipsed. Thus we find, that there will be an eclipse of the sun at the time of new moon in April 1764.

But the true time of that new moon comes out by the equations to be 50 minutes 46 feconds later than the mean time thereof, by comparing these times in the above example: and therefore we must add the sun's motion from the node during that interval to the above mean distance o' 5° 35′ 2″, which motion is sound in Table XII. for 50 minutes 46 seconds, to be 2′ 12″. And to this we must apply the equation of the sun's mean distance from the node in 'Table XV. found by the sun's anomaly, which, at the mean time of new moon in Example I. is 9's 1° 26′ 19′; and then we shall have the sun's true distance from the node, at the true time of new moon, as follows:

	Su	n fi	om N	ode.
	۵.	٥	,	"

Equation of mean diffance from]		2	5	0
Sun'struediffance from the alcend-	•	7	42	14

Which being far within the above limit of 17 degrees, shows that the fun must then be eclipsed.

And now we shall show how to project this, or any other eclipse, either of the sun or moon.

To project an Eclipse of the Sun.

In order to this, we must find the 10 following elements by means of the tables.

1. The true time of conjunction of the fun and moon; and at that time. 2. The femidiameter of the earth's disk, as feen from the moon, which is equal to the moon's horizontal parallax. 3. The fun's distance from the folstitial colure to which he is then nearest.

4. The sun's declination. 5. The angle of the moon's visible path with the ecliptic. 6. The moon's latitude.

7. The moon's true horary motion from the sun. 8. The sun's semidiameter. 9. The moon's. 10. The femidiameter of the penumbra.

We shall now proceed to find these elements for the sur's eclipse in April 1764.

To find the true time of new moon. This, by Example I. p. 562, is found to be on the first day of the faid month, at 30 minutes 25 seconds after ten in the morning.

2. To find the moon's horizontal parallax, or femidiameter of the earth's difk, as feen from the moon. Enter Table XVII. with the figure and degrees of the moon's anomaly (making proportions, because the anomaly is Of Calculain the table only to every 6th degree), and thereby take ting Eclipout the moon's horizontal parallax; which for the above time, answering to the anomaly 115 9° 24′ 21″,

is 54' 43".

3. To find the fun's diffance from the nearest folstice, viz. the beginning of Cancer, which is 3° or 90° from the beginning of Aries. It appears by Example I. on p. 566 (where the sun's place is calculated to the above time of new moon), that the sun's longitude from the beginning of Aries is then 0' 12' 10" 12": that is, the sun's place at that time is 7 Aries, 12' 10' 12'.

Therefore from - - 3 0 0 0 C Subtract the fun's longitude or place 0 12 10 12

Remains the fun's distance from \ the folstice \(\frac{1}{25} \)
Or 77° 49' 48"; each fign containing 30 degrees.

4. To find the fun's declination. Enter Table XIV. with the figns and degrees of the fun's true place, viz. os 12°, and making proportions for the 10' 12", take out the fun's declination answering to his true place, and it will be found to be 4° 49' north.

5. To find the moon's latitude. This depends on her

5. To find the moon's latitude. This depends on her distance from her ascending node, which is the same as the sun's distance from it at the time of new moon; and is thereby found in Table XVI.

But we have already found, that the fun's equated distance from the ascending node, at the time of new moon in April 1764, is 0' 7' 42' 14". See above.

Therefore, enter Table XVI. with o figns at the

Therefore, enter Table XVI. with o figns at the top, and 7 and 8 degrees at the left hand, and take out 36' and 39", the latitude for 7°; and 41' 51", the latitude for 8°: and by making proportions between these latitudes for the 42' 14", by which the moon's diffance from the node exceeds 7 degrees, her true latitude will be found to be 40' 18" north ascending.

6. To find the moon's true horary motion from the fun. With the moon's anomaly, viz. 115 9° 24' 21". Table XVII. and take out the moon's horary motion; which, by making proportions in that Table, will be found to be 30' 22". Then, with the fun's anomaly, 98 1° 26' 19", take out his horary motion 2' 28" from the fame table; and subtracting the latter from the former, there will remain 27' 54" for the moon's true horary motion from the sun.

7. To find the angle of the moon's visible path with the ecliptic. This, in the projection of eclipses, may be always rated at 5° 25', without any sensible error.

ways rated at 5° 35', without any fensible error.

8, 9. To find the semidiameters of the sun and moon. These are found in the same table, and by the same arguments, as their horary motions. In the present case, the sun's anomaly gives his semidiameters 16' 6', and the moon's anomaly gives her semidiameter 14' 57"

10. To find the semidiameter of the senumbra, Add the moon's semidiameter to the sun's, and their sum will be the semidiameter of the penumbra, viz. 31' 3".

Now collect these elements, that they may be found the more readily when they are wanted in the construction of this eclipse.

To project an Eclipse of the Sun geometrically.

Make a feale of any convenient length, as AC, and divide it into as many equal parts as the earth's femi-disk contains minutes of a degree; which, at the time of the celipse in April 1764. is 54' 53". Then, with the whole length of the scale as a radius, describe the semicircle AMB upon the centre C; which semicircle shall represent the northern half of the earth's enlightened disk, as seen from the sun.

Upon the centre C raise the straight line CH, perpendicular to the diameter ACB; so ACB shall be a

part of the ecliptic, and CH its axis.

Being provided with a good fector, open it to the radius CA in the line of chords; and taking from thence the chord of 23½ degrees in your compasses, set it off both ways from H, to g and to h, in the periphery of the semidisk; and draw the straight line g V h, in which the north pole of the disk will be always found.

When the fun is in Aries, Taurus, Gemini, Cancer, Leo, and Virgo, the north pole of the earth is enlightened by the fun: but whilft the fun is in the other fix figns, the fouth pole is enlightened, and the north pole is in the dark.

And when the fun is in Capricorn, Aquarius, Pifces, Aries, Taurus, and Gemini, the northern half of the earth's axis C XII P lies to the right hand of the axis of the ecliptic, as feen from the fun; and to the left hand, whilft the fun is in the other fix figns.

Open the scctor till the radius (or distance of the two 90's) of the sines be equal to the length of V b, and take the sine of the sun's distance from the soltice (77° 49' 48") as nearly as you can guess, in your compasses, from the line of the sines, and set off that distance from V to P in the line g V b, because the earth's axis lies to the right hand of the axis of the ecliptic in this case, the sun being in Aries; and draw the straight line C XII P for the earth's axis, of which P is the north pole. If the earth's axis had lain to the left hand from the axis of the ecliptic, the distance VP would have been set off from V towards g.

To draw the parallel of latitude of any given place, as suppose London, or the path of that place on the earth's enlightened disk as seen from the sun, from sunrise till sunset, take the following method.

Subtract the latitude of London, 51° from 90°, and the remainder 38° will be the colatitude, which the in your compasses from the line of chords, making

CA or CB the radius, and fet it from h (where the Of Calculate earth's axis meets the periphery of the disk) to VI and ing Echp11 and draw the occult or dotted line VI K VI.

Then, from the points where this line meets the earth's disk, set off the chord of the sun's declination 4° 49' to D and F, and to E and G, and connect these points by the two occult lines F XII G and DLE.

Bifect I.K XII in K, and through the point K draw the black line VI K VI. Then making CB the radius of a line of fines on the fector, take the colatitude of London 38°4 from the fines in your compaffes, and fet it both ways from K to VI and VI. These hours will be just in the edge of the disk at the equinoxes, but at no other time in the whole year.

With the extent K VI taken into your compasses, set one foot in K (in the black line below the occult one) as a centre, and with the other foot describe the semicircle VI 7 8 9 10, &c. and divide into 12 equal parts. Then from these points of division draw the occult lines 7p, 80, 9n, &c. parallel to the earth's axis C XII P.

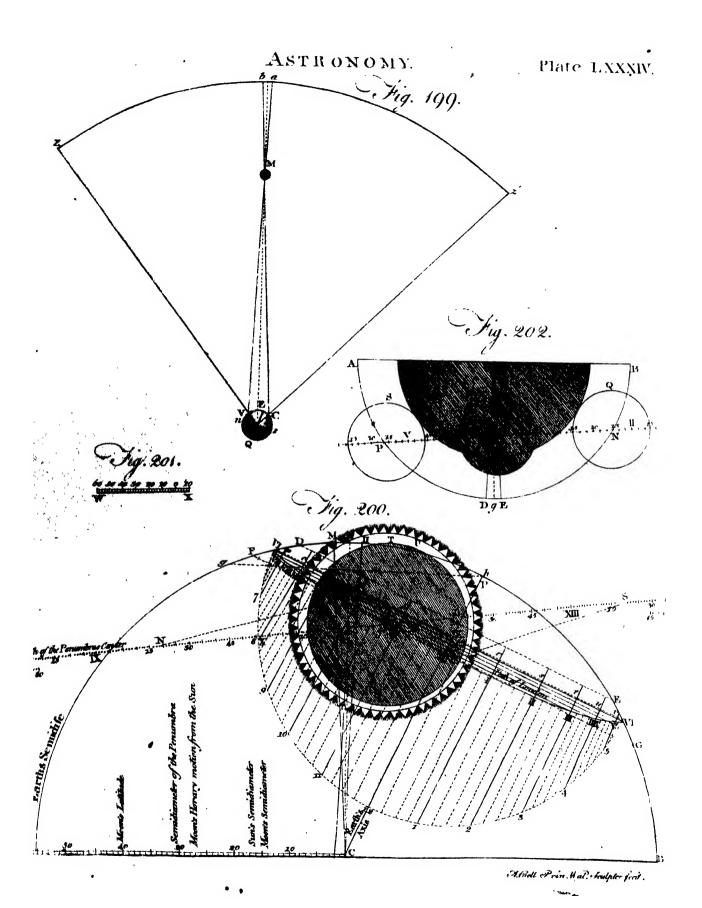

With the small extent K XII as a radius, describe the quadrantal arc XII f, and divide it into fix equal parts, as XII, a, ab, bc, cd, de, and cf; and through the division points a, b, c, d, e, draw the occult lines VII e V, VIII d IV, IX e III, X b II, and XI a I, and parallel to VI K VI, and meeting the former occult lines 7p 80, &c. in the points VII VIII IX X XI, V IV III II and I: which points that mark the several fituations of London on the search a diffe, at sheet hours respectively, as seen from the sum through these points, shall represent the parallel of latents, are infection on the disk, as seen from the land.

N. B. If the fun's declination and meet a sure the diurnal path of London would have been on sure appearance of the line VI K VI, and would have touched the line DLE in L. It is requisite to divide the horizon fpaces into quarters (as some are in the figure), and, at possible, into minutes also.

Make CB the radius of a line of chords on the fector, and taking therefrom the chord of 5° 35', the angle of the moon's visible path with the ecliptic, set it off from H to M on the left hand of CH, the axis of the ecliptic, because the moon's latitude is north ascending. Then draw CM for the axis of the moon's orbit, and bisect the angle MCH by the right line Cz. If the moon's latitude had been north descending, the axis of her orbit would have been on the right hand from the axis of the ecliptic.—N. B. The axis of the moon's orbit lies the same way when her latitude is south ascending as when it is north ascending; and the same way when south descending as when north descending.

Take the moon's latitude 40' 18" from the scale CA in your compasses, and set it from i to x in the bisecting line Cz, making in parallel to Cy: and through x, at right angles to the axis of the moon's orbit CM, draw the straight line N wxy S for the path of the penumbra's centre over the earth's disk.—The point w, in the axis of the moon's orbit, is that where the penumbra's centre approaches nearest to the centre of the earth's disk, and consequently in the middle of the general eclipse; the point x is that where the conjunction

tig. 200.

of Calculat- of the fun and moon falls, according to equal time by ng Echples, the tables; and the point y is the coliptical conjunction of the fun and moon.

> Take the moon's true horary motion from the fun. 27' 54", in your compasses, from the scale CA (every division of which is a minute of a degree), and with that extent make marks along the path of the penumbra's centre; and divide each space from mark to mark into 60 equal parts or horary minutes, by dots; and fet the hours to every both minute in such a manner, that the dot fignifying the instant of new moon by the tables may fall into the point x, half way between the axis of the moon's orbit and the axis of the ecliptic; and then the rest of the dots will show the points of the earth's disk, where the penumbra's centre is at the instants denoted by them, in its transit over the earth.

> Apply one fide of a square to the line of the penumbra's path, and move the square backwards and forwards until the other fide of it cuts the fame hour and minute (as at m and m) both in the path of London and in the path of the penumbra's centre; and the particular minute or instant which the square cuts at the same time in both paths shall be the instant of the visible conjunction of the sun and moon, or greatent obscuration of the sun, at the place for which the con-Queltion is made, minusty London, in the prefent exsimple and this inflant is at 47% minutes past ten o chock in the morning which is sy minutes five fo-

o'chick in the morning; which is 17 minutes five fecourse than the tubular time of true adaptaction.

The the first description of the grant for in your complaces were the first City and fetting one foot in the
mark the first City and fetting one foot in the

mark the first companies from London at the
remark the first description from the fame fcale,
which is the 4.7 minute after ten, with the other
foot the first TY for the moon's diffe, so
fore from London, at the time when the coliple is at
the greatest, and the portion of the fun's difk which is
the greatest, and the portion of the fun's difk which is
the greatest, and the moon's will show the quantity of and or ent off by the moon's will show the quantity of the ecliple at that time; which quantity may be meafured on a line equal to the fun's diameter, and divided

into 22 equal parts for digits.
Lamy, Take the femidiameter of the penumbra, 31'3", from the scale CA in your compasses; and setting one foot in the line of the penumbra's central path, on the left hand from the axis of the ecliptic, direct the other foot toward the path of London; and carry that extent backwards and forwards till both the points of the compuffes fall into the same instants in both the paths: and these instants will denote the time when the eclipse begins at London .- Then do the like on the right hand of the axis of the ecliptic; and where the points of the compasses fall into the same instants in both the paths, they will show at what time the eclipse ends at London.

These trials give 20 minutes after nine in the morning for the beginning of the eclipse at London, at the points N and O; 471 minutes after ten, at the points m and n, for the time of greatest obscuration; and 18 minutes after twelve, at R and S, for the time when the eclipfe ends; according to mean or equal time.

From these times we must substruct the equation of natural days, viz. 3 minutes 48 feconds, in leapyear April 1. and we shall have the apparent times;

Voz. II. Part II.

namely, 9 hours 16 minutes 12 feconds for the begin-Of Calculate ning of the eclipse, 10 hours 43 minutes 42 seconds for ing Felipses, the time of greatest obscuration, and 12 hours 14 minutes 12 feconds for the time when the eclipse ends. But the best way is to apply this equation to the true equal time of new moon, before the projection be begun; as is done in Example I. For the motion or polition of places on the earth's disk answer to apparent or solar time.

In this construction it is supposed, that the angle under which the moon's disk is seen, during the whole time of the ecliple, continues invariably the same; and that the moon's motion is uniform and rectilineal during that time. But thele suppositions do not exactly agree with the truth; and therefore, supposing the elements given by the tables to be accurate, yet the times and phases of the eclipse, deduced from its construction, will not answer exactly to what passeth in the heavens; but may be at least two or three minutes wrong, though done with the greatest care. Moreover, the paths of all places of confiderable latitudes are nearer the centre of the earth's disk as scen from the fun than those constructions make them; because the disk is projected as if the earth were a perfect sphere, although it is known to be a spheroid. Consequently, the moon's shadow will go farther northward in all places of northern latitude, and farther fouthward in all places of fouthern latitude, than it is shown to do in these projections .- According to Meyer's Tables, this eclipfe was about a quarter of an hour fooner than either these tables, or Mr Flamstead's, or Dr Halley's, make it; and was not annular at London. But M. de la Caille's make it almost central.

The projection of lunar eclipses.

When the moon is within 12 degrees of either of her nodes at the time when the is full, the will be eclipfed, otherwise not.

We find by Example II. page 562, that at the time of mean full moon in May 1762, the fun's distance from the ascending node was only 4° 49' 35"; and the moon being then opposite to the fun, must have been just as near her descending node, and was therefore eclipsed.

The elements for constructing an eclipse of the moon are eight in number, as follow:

1. The true time of full moon; and at that time, 2. The moon's horizontal parallax. 3. The fun's femidiameter. 4. The moon's. 5. The semidiameter of the earth's shadow at the moon. 6. The moon's latitude. 7. The angle of the moon's visible path with the ecliptic. 8. The moon's true horary motion from the fun. - Therefore.

1. To find the true time of new or full moon. Work as already taught in the precepts.—Thus we have the true time of full moon in May 1762 (fee Example II. page 562) on the 8th day, at 50 minutes 50 seconds past three o'clock in the morning.

2. To find the moon's horizontal parallax. Enter Table XVII. with the moon's mean anomaly (at the above full) 95 20 42' 42", and thereby take out her horizontal parallax; which, by making the requilite proportions, will be found to be 57' 23'

3, 4. To find the femidiameters of the fun and moon. Enter Table XVII. with their respective anomalies, the fun's being 10' 7° 27' 45" (by the above example) and the moon's 9' 2" 42' 42"; and thereby take out their respective semidiameters; the sun's 15' 56", and the moon's 15' 38".

481

Of Calculat-5. To find the semidiameter of the earth's shadow at the ing Eclipses, moon. Add the fun's horizontal parallax, which is always 10", to the moon's, which in the prefent cafe is 37' 23", the sum will be 57' 33", from which subtract the sun's semidiameter 15' 56", and there will remain 476

41' 37" for the semidiameter of that part of the earth's

shadow which the moon then passes through.

6. To find the moon's latitude. Find the fun's true distance from the ascending node (as already taught in page 566) at the true time of full moon; and this distance increased by fix signs will be the moon's true distance from the same node; and consequently the argument for finding her true latitude, as shown in p. 566.

Thus, in Example II. the fun's mean distance from the ascending node was of 4° 49' 35", at the time of mean full moon; but it appears by the example, that the true time thereof was fix hours 33 minutes 38 feconds fooner than the mean time; and thereof we must subtract the sun's motion from the node (found in Table XII.) during this interval, from the above mean distance of 4° 49' 35", in order to have his mean distance from it at the true time of full moon. Then to this apply the equation of his mean distance from the node, found in Table XV. by his mean anomaly 10 7° 27' 45"; and lastly add fix figns: fo shall the moon's true distance from the ascending node be found as follows:

Sun from node at mean full moon	0	4	49	35
His motion from it in 6 hours 33 minutes 38 feconds				35 26 2
Sum, subtract from the uppermost line			17	3
Remains his mean distance at true full moon Equation of his mean distance, add	0	4	32 38	
Sun's true distance from the node To which add	6	6	10	32 0
And the fum will be	6	6	10	32

Which is the moon's true distance from her ascending node at the true time of her being full; and confequently the argument for finding her true latitude at that time. -Therefore, with this argument enter Table XVI. making proportions between the latitudes belonging to the 6th and 7th degree of the argument at the left hand (the figns being at top) for the 10' 32", and it will give 32' 21" for the moon's true latitude, which appears by the table to be fouth descending.

7. To find the angle of the moon's visible path with the ecliptic. This may be stated at 5° 35', without any error of consequence in the projection of the eclipse.

8. To find the moon's true horary motion from the Jun. With their respective anomalies take out their horary motions from Table XVII. and the fun's horary motion fubtracted from the moon's, leaves remaining the moon's true horary motion from the fun: in the present case 30' 52".

Now collect these elements together for use.

D. H. M. S. 1. True time of full moon in May 1762 8 3 50 50 0 1 11 a mioon's horizontal parallax 0 57 23 0 15 56 📤 Moon's femidiameter O 15 38 Semidiameter of the earth's shadow at the moon construction and state and st O 41 37 0 32 21 5 35 0 These elements being found for the construction of the moon's ecliple in May 1762, proceed as follows:

Make a scale of any convenient length, as WX Oscalculated "(fig. 201.), and divide it into 60 equal parts, each part ing Ecliptes, standing for a minute of a degree.

Draw the right line ACB (fig. 201.) for part of the ecliptic, and CD perpendicular thereto for the fouthern part of its axis; the moon having fouth latitude.

Add the femidiameters of the moon and earth's shadow together, which in this eclipse will make 57' 15"; and take this from the scale in your compasses, and letting one foot in the point C as a centre, with the other foot describe the semicircle ADB; in one point of which the moon's centre will be at the beginning of the eclipse, and in another at the end thereof.

Take the femidiameter of the earth's shadow, 41' 37". in your compasses from the scale, and setting one foot in the centre C, with the other foot describe the semicircle KLM for the fouthern half of the earth's shadow, because the moon's latitude is south in this eclipse.

Make CD equal to the radius of a line of chords on the fector, and fet off the angle of the moon's visible path with the ecliptic, 5° 35', from D to E, and draw, the right line CFE for the fouthern half of the axis of the moon's orbit lying to the right hand from the axis of The ecliptic CD, because the moon's latitude is south descending .- It would have been the same way (on the other fide of the ecliptia) if her latitude had been north descending, but contrary in both cases if her latitude had been either north alcending or losth doesding,

Bilect the angle DCE by the right line Ce, in which line the true equal time of opposition of the first and moon falls as given by the zables.

Take the moon's latitude, 35 27% from the foale with your compelles, and fet it from C on G in the line CG g; and through the point G, at right angles to CFE, draw the right line PHGFN for the point of the moon's centre. Then F shall be the point in the earth's shadow, where the moon's centre is at the middle of the ecliple; G, the point where her centre is at the tabular time of her being full; and H, the point where her centre is at the inflant of her ecliptical opposition.

Take the moon's horary motion from the fun, go 52", in your compasses from the scale; and with that extent make marks along the line of the moon's math PGN: then divide each space from mark to mark into 60 equal parts, or horary minutes, and let the hours to the proper dots in such a manner, that the design nifying the instant of full moon (viz. 50 migutes 50 feconds after III. in the morning) may be in the point G, where the line of the moon's path cuts the line that bifects the angle DCE.

Take the moon's semidiameter, 15' 38", in your compasses from the scale, and with that extent, as a radius, upon the points N, F, and P, as centres, describe the circle Q for the moon at the beginning of the eclipse, when she touches the earth's shadow at V; the circle R for the moon at the middle of the eclipse; and the circle S for the moon at the end of the eclipse, just leaving the earth's shadow at W.

The point N denotes the inflant when the eclipse began, namely, at 15 minutes 10 feconds after II in the morning; the point F the middle of the eclipse at 47 minutes 44 feconds past III; and the point P the end of the eclipse, at 18 minutes after V .- At the greatest obscuration the moon was 10 digits eclipsed.

Jupiter's SECT. XI. The Method of finding the Longitude by the Ellipses of Jupiter's Satellites; the amazing Velocity of Light demonstrated by these Eclipses; and of Cometary Eclipses.

. In the former fection having explained at great length how eclipses of the fun and moon happen at certain times, it must be evident, that similar eclipses will be observed by the inhabitants of Jupiter and Saturn, which are attended by so many moons. These Frequency eclipfes indeed very frequently happen to the fatellites of thefe e. of Jupiter; and as they are of the greatest service in determining the longitudes of places on this earth. astronomers have been at great pains to calculate tables for the eclipses of these satellites by their primary, for the fatellites themselves have never been observed to eclipse one another. The construction of such tables is indeed much easier for these satellites than of any other celeftial bodies, as their motions are much more

regular.
The English tables are calculated for the meridian of Greenwich, and by these it is very easy to find how many degrees of longitude any place is distant either est or west from Greenwich; for, let an observer, the has their tables, with a good telefcope and a will regulated clock at any other place of the earth, otherwise the finance ending of an eclipfe of one of the case of the precise moment of the number of the stables and compare that time that the stables for Greenwich is allowed. The tables for Greenwich is allowed of time, will give the tables are very minute a quarter of the stables are very constant of they are tables are very constant of they happen who has their tables, with a good telefcope and a is discliples are very con-tand, because they happen out the of no sign fea, because the the hap tanders all nice telescopical observa-

The explain this by a figure, let I be Jupiter, K, L, M; his four fatellites in their respective orbits, Fig. 277. 2, 3, 4; and let the earth be at F (Suppose in Nowamber, although that month is no otherwise mate-Friel than to find the earth readily in this scheme, where it is shown in eight different parts of the orbit). Let O be a place on the meridian of Greenwich, and R a place on some other meridian eastward from Greenwich. Let a person at R observe the instantaneous vanishing of the first satellite K into Jupiter's shadow, suppose at three o'clock in the morning; but by the tables he finds the immersion of that setellize to be at midnight at Greenwich; he then can immediately determine, that as there are three hours difference of time between Q and K, and that R is three hours forwarder in reckoning than Q, it must be 45 degrees of east longitude from the meridian of Q. Were this method as practicable at fea as at land, any failor might almost mmerfions as cafily, and with equal certainty, find the longitude as the latitude.

Whilst the earth is going from C to F in its orbit, only the immersions of Jupiter's satellites into his sha-Vol. II. Part II.

dow are generally feen; and their emersions out of it Eclipses of while the earth goes from G to B. Indeed, both these Jupiter's appearances may be feen of the fecond, third, and Satelites. fourth fatellite when eclipfed, whilst the earth is between D and E, or between G and A; but never of the first latellite, on account of the imallness of its orbit and the bulk of Jupiter, except only when Jupiter is directly opposite to the fun, that is, when the earth is at G; and even then, strictly speaking, we cannot see either the immersions or emersions of any of his satellites, because his body being directly between us and his conical shadow, his fatellites are hid by his body a few moments before they touch his shadow; and are quite emerged from theuce before we can fee them, as it were just dropping from him. And when the carth is at C, the sun, being between it and Jupiter, hides both him and his moons from us.

In this diagram, the orbits of Jupiter's moons are drawn in true proportion to his diameter; but in proportion to the earth's orbit, they are drawn vaffly too

In whatever month of the year Jupiter is in conjunction with the fun, or in opposition to him, in the next year it will be a month later at least. For whilst the earch goes once round the fun, Jupiter describes a twelfth part of his orbit. And therefore, when the earth has fireffied its annual period, from being in a line with the fun and Jupiter, it must go as much forwarder as Jupiter has moved in that time, to overtake him again; just like the minute hand of a watch, which must, from any conjunction with the hour hand, go once round the dialplate and somewhat above a twelfth part more, to overtake the hour hand again.

It is found by observation, that when the earth is velocity of between the fun and Jupiter, as at G, his fatellites are light. eclipfed about 8 minutes fooner than they should be according to the tables; and when the earth is at B or C, thefe ecliples happen about 8 minutes later than the tables predict them. Hence it is undeniably certain, that the motion of light is not instantaneous, fince it takes about 16; minutes of time to go through a space equal to the diameter of the earth's orbit, which is 180,000,000 of miles in length; and confequently the particles of light fly almost 200,000 miles every fecond of time, which is above a million of times swifter than the motion of a cannon bullet. And as light is 16' minutes in travelling across the earth's orbit, it must be 81 minutes in coming from the fun to us: therefore if the fun were annihilated, we should fee him for 84 minutes after; and if he were again created, he would be 84 minutes old before we could fee him.

To illustrate this progressive motion of light, let A and B be the earth in two different parts of its orbit, whose distance from each other is 95,000,000 of miles, equal to the earth's diffance from the fun S. It is Fig. 178 plain, that if the motion of light were inflantaneous, the fatellite I would appear to enter into Jupiter's shadow FF at the same moment of time to a spectator in A, as to another in B. But by many years observetions it has been found, that the immertion of the fatellite into the shadow is seen 8; minutes sooner when the earth is at B than when it is at A. And fo, as Mr Romeur first discovered, the motion of light is thereby proved to be progressive, and not instanta-

When the or emerlions are to be ob.

crved.

Ecupies of neous, as was formerly believed. It is eafy to com-Jupiter's pute in what time the earth moves from A to B; for Swiellites, the chord of any degree of any circle is equal to the femidiameter of that circle: and as the earth goes through all the 360 degrees of its orbit in a year, it goes through 60 of those degrees in about 61 Adays. Therefore, if on any given day, suppose the first of June, the earth is at A, on the first of August it will be at B; the chord, or ftraight line AB, being equal to DS the radius of the earth's orbit, the same with AS its diffance from the fun.

> As the earth moves from D to C thro' the fide AB of its orbit, it is conflantly meeting the light of Jupiter's fatellites fooner, which occasions an apparent acceleration of their eclipses; and as it moves through the other half H of its orbit, from C to D, it is receding from their light, which occasions an apparent retardation of their eclipses, because their light is then longer before it overtakes the earth.

485 Accelera-

That these accelerations of the immersions of Jupiter's fatellites into his shadow, as the earth approaches these eclip- to wards Jupiter, and the retardations of their emersions fes not ow- out of his shadow, as the earth is going from him, are ing to any not occasioned by any inequality arising from the moin the mo. tions of the fatellites in eccentric orbits, is plain, betions of the cause it affects them all alike, in whatever parts of their fatellites. orbits they are eclipfed. Eclides, they go often round their orbits every year, and their motions are no way commensurate to the earth's. Therefore a phenomenon not to be accounted for from the real motions of the fatellites, but fo easily deducible from the earth's motion, and fo answerable thereto, must be allowed to refult from it. This affords one very good proof of

486 Ecliptes by contets.

the carth's annual motion. From what we have faid in general concerning eclipses, it is plain that secondary planets are not the only bodies that may occasion them. The primary planets would eclipfe one another, were it not for their great distances; but as the comets are not subject to the same laws with the planets, it is possible they may fometimes approach fo near to the primary planets, as to cause an eclipse of the sun in those planets; and as the body of a comet bears a much larger proportion to the bulk of a primary planet than any secondary, it is plain that a cometary ecliple would both be of much longer continuance, and attended with much greater darknels, than that occasioned by a secondary planet. This behaved to be the case at any rate: but if we suppose the primary planet and comet to be moving both the fame way, the duration of fuch an eclipfe would be prodigiously lengthened; and thus, instead of four minutes, the fun might be totally darkened to the inhabitants of certain places for as many hours. Hence we may account for that prodigious darkness which we fometimes read of in luftory at times when no eclipfe of the fun by the moon could possibly happen. It is remarkable, however, that no comet hath ever been obferved paffing over the disk of the fun like a spot, as Venus and Mercury are; yet this must certainly happen, when the comet is in its perihelion, and the earth on the same side of its annual orbit. Such a phenomenon well deferves the watchful attention of aftronomers, as it would be a greater confirmation of the planetary nature of comets than any thing hitherto obferved.

SECT. XII. A Description of the Astronomical Ma-mical Machinery ferving to explain and illustrate the fore- chinery. going part of this Treatife.

487

THE machine represented by fig. 207. is the GRAND ORRERY, first made in this kingdom by Mr Rowley for King George I. The frame of it, which contains the wheel-work, &c. and regulates the whole machine is made of ebony, and about four feet in diameter; the outfide thereof is adorned with 12 pilattres. Between thefe the 12 figns of the zodiac are neatly painted with gilded frames. Above the frame is a broad ring supported with 12 pillars. This ring represents the plane of the ecliptic; upon which are two circles of degrees, and between these the names and characters of the 12 figns. Near the outfide is a circle of months and days, exactly corresponding to the fun's place at hoon each day throughout the year. Above the ecliptic stand some of the principal circles of the sphere, agreeable to their respective situations in the heavens a viz. No 10. are the two colures, divided into degrees and half degrees; No 11 is one-half of the equinoctial circle, making angles of 234 degrees. The tropic of Cancer and the arctic circle are each fixed parallel at their proper diftance from the equinoctial. On the northern half of the ecliptic is a brais femicircle, moveable upon two points fixed in an and . This femicircle ferves as a moveable floriant to be partied any degree of latitude upon the most part of the moridian, and the whole machine may be fet to any later tude without disturbing any of the internal motion by two strong hinges (No. 13.) fixed to the internal process frame upon which the influencest mores, and a brain brain arch, having holes at every degree, therein arch and the two hinges support the whole mandless. when it is lifted up according to any labetude, and the arch at other times less conveniently under the bottom frame. When the machine is let so may latitude (which is cally done by two men, each taking hald of two handles conveniently fixed for the purpole), let the moveable horizon to the fame degree upon the man ridian, and hence you may form an idea of the refuertive latitude or depression of the planets both primary and fecondary. The fun (No 1.) stands in the middle of the whole fystem upon a wire, making an angle with the ecliptic of about 82 degrees. Next the fun is a fmall ball (2.) representing Mercury. Next to Mercury is Venus (3.) represented by a larger ball. The earth is represented (N° 4.) by an ivory ball, having fome circles and a map sketched upon it. The wire which supports the earth makes an angle with the ecliptic of 661 degrees, the inclination of the earth's axis to the ecliptic. Near the bottom of the earth's axis is a dialplate (No 9.) having an index pointing to the hours of the day as the earth turns round its axis. Round the earth is a ring supported by two fmall pillars reprefenting the orbit of the moon; and the divisions upon it answer to the moon's latitude. The motion of this represents the motion of the moon's orbit according to that of the nodes. Within this ring is the moon (N° 5.), having a black cap or case, by which its motion represents the phases of the moon according to her age. Without the orbits of

chinery.

. Astrono- the earth and moon is Mars (No 6.) The next in ormical Ma-der to Mars is Jupiter and his four moons (No 7.) chinery. Each of these moons is supported by a wire fixed in a focket which turns about the pillar supporting Supiter. These satellites may be turned by the handto any pofition, and yet when the machine is put into motion, they will all move in their proper times. The outermost of all is Saturn, his five moons, and his ring (Nº 8.) These moons are supported and contrived fimilar to those of Jupiter. The machine is put into motion by turning a small winch (No 14.); and the whole fystem is also moved by this winch, and by pulling out and pushing in a small cylindrical pin above the handle. When it is pushed in, all the planets, both primary and fecondary, will move according to their respective periods by turning the handle. When it is drawn out, the motions of the satellites of Jupiter and Saturn will be stopped while all the rest move without interruption. There is also a brass lamp, having two convex glasses to be put in room of the sun; and also a smaller earth and moon, made somewhat in proportion to their distance from each other, which may be put on at pleasure. The lamp turns round at the lame time with she earth, and the glaffes of it call a firong light upon and the games of the arth and snoon are placed on a will be easily to thou when either of them will be easily to thou when either of them will be esting and When this machine is intended to be seen the allower and he dolly placed by means of an ephement. Accepted a described; and you may place a will black success or he of water upon the middle of he fan, the state was the first degree of w, you allow he will be successful to the first degree of w, you will be a state with the first degree of w, you will be a state with the same will be successful to the ecliptic. Put the state was successful to the ecliptic. Put which is above it.

The same will be a state of the ecliptic and the same will be a shown by the same will be her Mad when the finaller earth and moon are plaplacets and their motions round their own axes, tions of the spots upon the surface of the sun and of the planets in the heavens, their diurnal was first difcovered, after the same manner as we in this machine observe the motions of their representatives by that of the marks placed upon them.

The ORRERY (fig. 208.) is a machine contrived by the late ingenious Mr James Ferguson. It shows the motions of the fun, Mercury, Venus, Earth, and Moon; and occasionally the superior planets, Mars, Jupiter, and Saturn, may be put on. Jupiter's four satellites are moved round him in their proper times by a small winch: and Saturn has his five fatellites, and his ring which keeps its parallelism round the sun; and by a lamp put in the fun's place, the ring shows all its various phases already described.

In the centre, No 1. represents the fun supported by its axis, inclining almost 8 degrees from the axis of the ecliptic, and turning round in 251 days on its axis, of which the north pole inclines toward the eighth degree of Pisces in the great ecliptic (No 11.), whereon the months and days are engraven over the figns and

degrees in which the fun appears, as feen from the Aftronoearth, on the different days of the year.

The nearest planet (No 2.) to the sun is Mercury, which goes round him in 87 days 23 hours, or 87 11 diurnal rotations of the earth; but has no motion round its axis on the machine, because the time of its diurnal motion in the heavens is not known to us.

The next planet in order is Venus (No 3.), which performs her annual course in 224 days 17 hours, and turns round her axis in 24 days 8 hours, or in 24; diurnal rotations of the earth. Her axis inclines 75 degrees from the axis of the ecliptic, and her north pole inclines towards the 20th degree of Aquarius according to the observations of Bianchini. She shows all the phenomena described in Sect. 11.

Next, without the orbit of Venus, is the earth (No 4.), which turns round its axis, to any fixed point at a great distance in 23 hours 56 minutes 4 seconds of mean folar time; but from the fun to the fun again, in 24 hours of the same time. No 6. is a sidereal dial plate under the earth, and No 7. a folar dialplate on the cover of the machine. The index of the former shows sidereal, and of the latter, solar time; and hence the former index gains one entire revolution on the latter every year, as 365 folar or natural days contain 366 fidereal days, or apparent revolutions of the flars, In the time that the earth makes 365; diurnal rotations on its axis, it goes once round the fun in the plane of the ecliptic; and always keeps opposite to a moving index (No 10.) which shows the fun's daily change of place, and also the days of the months.

The earth is half covered with a black cap, for dividing the apparently enlightened half next the fun from the other half, which, when turned away from him, is in the dark. The edge of the cap reprefents the circle bounding light and darkness, and shows at what time the fun rifes and fets to all places throughout the year. The earth's axis inclines 23 to degrees from the axis of the ecliptic; the north pole inclines toward the beginning of Cancer, and keeps its parallelism throughout its annual course; so that in summer the northern parts of the earth incline towards the fun, and in winter from him: by which means the different length of days and nights, and the cause of the various seasons, are demonstrated to fight.

There is a broad horizon, to the upper fide of which is fixed a meridian femicircle in the north and fouth points graduated on both fides from the horizon to 90° in the zenith or vertical point. The edge of the horizon is graduated from the east and west to the foutle and north points, and within these divisions are the points of the compais. From the lower fide of this thin horizontal plate stand out four small wires, to which is fixed a twilight circle 18 degrees from the graduated fide of the horizon all round. This horizon may be put upon the earth (when the cap is taken away), and rectified to the latitude of any place; and then by a fmall wire called the folar ray, which may be put on to as to proceed directly from the fun's centre towards the earth's, but to come no farther than almost to touch the horizon, the beginning of twilight, time of funrifing, with his amplitude, meridian altitude, time of fetting, amplitude then, and end of twilight, are shown for every day of the year, at the place to which the horizon is rectified.

Astronomi- The moon (No 5.) goes round the earth, from becal Machi-tween it and any fixed point at a great distance, in 27 days 7 hours 43 minuties, or through all the figns and degrees of her orbit, which is called her periodical revolution; but the goes round from the fun to the fun again, or from change to change, in 20 days 12 hours 35 minutes, which is her fynodical revolution; and in that time the exhibits all the phases already described.

> When the above-mentioned horizon is rectified to the latitude of any given place, the times of the moon's rifing and fetting, together with her amplitude, are shown to that place as well as the fun's; and all the various phenomena of the harvest moon are made obvious to

fight.

The moon's orbit (No 9.) is inclined to the ecliptic (No 11.), one half being above, and the other below it. The nodes, or points at o and o, lie in the plane of the ecliptic, as before described, and shift backward through all its fines and degrees in 187 years. The degrees of the moon's latitude to the highest at NL (north latitude) and lowest at SL (south latitude, are engraven both ways from her nodes at o and o, and as the moon rifes and falls in her orbit according to its inclination, her latitude and diffances from her nodes are shown for every day, having first rectified her or-I it fo as to fet the nodes to their proper places in the celiptic; and then as they come about at different and almost opposite times of the year, and then point towards the fun, all the celipfes may be shown for huncreds of years (without any new reclification), by turning the machinery backward for time palt, or forward for time to come- At 17 degrees distance from each node, and both fides, is engraved a finall fun; and at 12 degrees distance, a small moon, which show the limits of folar and lunar eclipfes; and when, at any change, the moon falls between either of these suns and the node, the fun will be eclipfed on the day pointed to by the annual index (No 10.); and as the moon has then north or fouth latitude, one may eafily judge whether that eclipfe will be visible in the northern or fouthern hemisphere; especially as the earth's axis inchies toward the fun or from him at that time. And when at any full the moon falls between either of the little moons and node, she will be eclipsed, and the annual index shows the day of that cclipse. There is a circle of 291 equal parts (No 8.) on the cover of the machine, on which an index shows the days of the moon's age.

There are two semicircles (fig. 216.) fixed to an elliptical ring, which being put like a cap upon the earth, and the forked part F upon the moon, shows the tides as the earth turns round within them, and they are led round it by the moon. When the different places come to the semicircle AaEbB, they have tides of flood; and when they come to the femicircle CED, they have tides of ebb; the index on the hour circle (fig. 208.) showing the times of these phenomena.

There is a jointed wire, of which one end being put ipto a hole in the upright stem that holds the earth's cap, and the wire laid into a small forked piece which may be occasionally put upon Venus or Mercury, shows the direct and retrograde motions of these two planets, with their stationary times and places, as feen from the carth.

The whole machinery is turned by a winch or handle Aftronomi-(Nº 12.); and is so catily moved, that a clock might cal Machiturn it without any danger of flopping.

To give a plate of the wheel work of this machine would answer no purpose, because many of the wheels lie so behind others as to hide them from fight in any

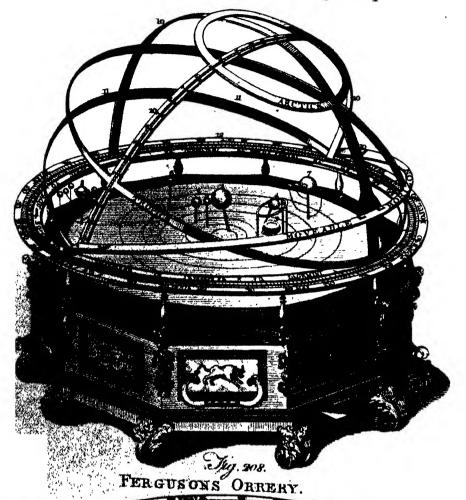

view whatever.

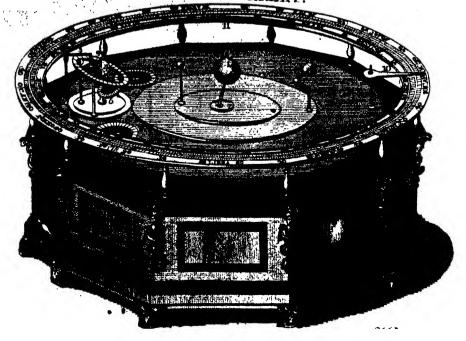

The PLANETARIUM (fig. 209.) is an instrument contrived by Mr William Jones of Holborn, London, mathematical infirmment maker, who has paid confiderable attention to those fort of machines, in order to reduce them to their greatest degree of simplicity and perfection. It represents in a general manner, by various parts of its machinery, all the motions and phenomena of the planetary fyttem. This machine confifts of, the Sun (in the centre), with the planets, Mercury, Venus, the Earth and Moon, Mars, Jupiter, and his four moons, Satura and his five moons; and to it is occasionally applied an extra long arm for the Georgian planet and his two moons. To the earth and moon is applied a frame CD, containing only four wheels and two pinions, which ferre to preferre the earth's axis in its proper parallelism in its motion round the fun, and to give the moon ber due revolution about the earth at the fame time. These wheels are connected with the wheel work in the round box below, and the whole is fet in motion by the winch H. arm M that carries round the moon, prints out on the bit, and which accordingly are engraved thereon. the same manner the sem points and for place in the ecliptic B, in signs and degrees, taken her government place; that is, as seen from the cards. The months place; that is, as seen seen; the certification is misconorbit is represented by the dat rine of a the two justice
of which, and upon which it runts directing the addition.
This orbit is made to design as may defined wight.
The earth of this infurment is already made of a trivial
inch or a globe, papered, the for the purpose, and
by means of the recognitions who that great over it,
points out the changes of the feature, and the different lengths of days and nights more conspicuously. This machine is also made to represent the Ptolemaic Sys stem, or such as is vulgarly received; which places the earth in the centre, and the planets and fun revolving about it. (It is done by an auxiliary small fun and an earth, which change their places in the inftrument.) At the same time, it affords a most manifest confuture tion of it; for it is plainly observed in this construction, (1.) That the planets Mercury and Venus being both within the orbit of the fun, cannot at any time be feen to go behind it; whereas in nature we observe them as often to go behind as before the fun in the heavens. (2.) It shows, that as the planets move in circular orbits about the central earth, they ought at all times to be of the same apparent magnitude; whereas, on the contrary, we observe their apparent magnitude in the heavens to be very variable, and for far different, that, for instance, Mars will sometimes appear as big as Jupiter nearly, and at other times you will scarcely know him from a fixed star. (3.) It shows that any of the planets might be seen at all distances from the fun in the heavens; or, in other words, that when the fun is fetting, Mercury or Venus may be feen not only in the fouth but even in the east; which circumstances were never yet observed.

Fig. 207. The GRAND ORRERY byRowley.

Aftrono- You see by this planetarium that the motions of the mical Ma- planets should always be regular and uniformly the chenery. fame; whereas, on the contrary, we observe them always to move with a variable velocity, fometimes faster, then flower, and fometimes not at all, as will be prefently shown. (5.) By the machine you see the planets move all the fame way, viz. from well to east continually; but in the heavens we fee them move fometimes direct from well to eath, fometimes retrograde from east to well, and at other times to be stationary. All which phenomena plainly prove this fystem to be

a falfe and abfurd hypothelis. The truth of the Copernican or Solar System of the world is hereby most clearly represented. For taking the earth from the centre, and placing thereon the usual large brass ball for the sun, and restoring the earth to its proper lituation among the planets, then every thing will be right, and agree exactly with celestial observations. For turning the winch H, (1.) You will fee the planets Mercury and Venus go both before and behind the fun, or have two conjunctions. (2.) You will observe Mercury never to be more than a certain angular diffance, 21°, and Venus 47°, from the fun. (3.) That the planets, especially Mars, will he sametimes much nearer to the earth than at others, therefore must appear larger at one time than at therefore must appear larger at one time than at spitister. (4.) You will see that the planets cannot appear at the earth to move with an uniform velocity; for which accepts they appear to move faster, and flower than accepts they appear to move sometimes directly the well to see that to move some retrograde from the particular to become retrograde from the particular than the particular the particular than the particular inca put in motion, the planet D, as feen in the from the earth at F, will undergo the feveral prop that is over Mercury at E, may be placed over the other superior planets, Mars, &c. and the same phenomena be exhibited.

By this machine you at once see all the planets in motion about the fun, with the same respective velocities and periods of revolution which they have in the heavens; the wheel work being calculated to a minute of time, from the latest discoveries.

You will see here a demonstration of the earth's motion about the fun, as well as those of the rest of the planets: for if the earth were to be at rest in the heavens, then the time between any two conjunctions of the fame kind, or oppositious, would be the same with the periodical time of the planets, viz. 88 days in Mercury, 225 in Venue, &c.: whereas you here observe this time, instead of being 225 days, is no less than 583 days in Venue, occasioned by the earth's moving in the mean time about the fun the fame way with the planet. And this space of 583 days always passes between two like conjunctions of Venus in the heavens. Hence the most important point of astrono. Astronomy is fatisfactorily demonstrated.

The diurnal rotation of the earth about its axis, and a demonstration of the cause of the different seafons of the year, and the different lengths of days and nights, are here answered completely: for as the earth is placed on an axis inclining to that of the ecliptic in an angle of 231 degrees, and is fet in motion by the wheel-work, there will be evidently feen the different inclination of the fun's rays on the earth, the different quantity thereof which falls on a given space, the different quantity of the atmosphere they pass through, and the different continuance of the fun above the horizon at the same place in different times of the year; which particulars conflitute the difference betwixt heat and cold in the fummer and winter feafons.

As the globe of the earth is moveable about its inclined axis, so by having the horizon of London drawn upon the surface of it, and by means of the terminating wire going over it, by which is denoted, that on that fide of the wire next the fun is the enlightened half of the earth, and the opposite side the darkened half, you will here fee very naturally represented the cause of the different lengths of day and night, by obferving the unequal portions of the circle which the island of Great Britam, or the city of London, or any other place, describes in the light and dark hemispheres at different times of the year, by turning the earth on its axis with the hand. But in some of the better orreries on this principle, the earth revolves about its axis by wheel-work.

As to the eclipies of the fun and moon, the true causes of them are here very clearly seen: for by placing the lamp (fig. 212.) upon the centre, in room of the brass ball denoting the fun, and turning the winch until the moon comes into a right line between the centres of the lamp (or fun) and earth, the shadow of the moon will fall upon the earth, and all who live on that part over which the shadow passes will see the fun eclipsed more or less. On the other fide, the moon passes (in the aforesaid case) through the shadow of the earth, and is by that means eclipfed. And the orbit A (fig. 210.) is so moveable on the two joints called nodes, that any person may easily represent the due position of the nodes and intermediate spaces of the moon's orbit; and thence show when there will or will not be an eclipse of either luminary, and what the quantity of each will be.

While the moon is continuing to move round the earth, the lamp on the centre will so illumine the moon, that you will easily fee all her phases, as new, dichotomized, gibbous, full, waning, &c. just as they appear in the heavens. You will moreover observe all the same phases of the earth as they appear at the moon.

The fatellites of Jupiter and Saturn are moveable only by the hand; yet may all their phenomena be eafily reprefented, excepting the true relative motions and distances. Thus, if that gilt globe which before represented the sun be made now to denote Jupiter, and four of the primary planets only be retained, then will the Jovian fystem be represented; and by candle light only you will fee (the machine being in motion) the immersions and emersions of the satellites into and out of Jupiter's shadow. You will see plainly the manner in which they transit his body, and their oc-

cultations.

490

Astronomi- cultations behind it. You will observe the various cal Machi- ways in which one or more of these moons may at times disappear. And if the machine be fet by a white wall, &c. then by the projection of their shadows will be feen the reasons why those moons always appear on each fide of Jupiter in a right line, why those which are most remote may appear nearest, and è contrario. And the same may be done for Saturn's five moons and his ring.

> The method of Rectifying the Orrery, and the proper Manner of placing the Planets in their true Situa-

Having dwelt thus much on the description of orreries, it may be useful to young readers, to point out the method by which the orrery should be first rectified, previous to the exhibition or using of it: and the following is extracted from Mr William Jones's description of his new Portable Orrery. " The methed of showing the places, and relative aspects of the

planets on any day of the year in the planetarium, Aftronom must be done by the assistance of an ephemeris or alma- cal Much nack, which among other almanacks is published annually by the Stationers Company.

"This ephemeris contains a diary or daily account of the planets places in the heavens, in figns, degrees, and minutes, both as they appear to the eye supposed to be at the fun, and at the earth, throughout the year. The first of these positions is called the believentric place, and the latter, the geocentric place. The beliocentric place is that made use of in orreries; the geocentric place, that in globes. As an example for finding their places, and fetting them right in the orrery, we will suppose the ephemeris (by White, which for this purpose is confidered the bell) at hand, wherein at the bottom of the left-hand page for every month is the heliocentric longitudes (or places) of all the planets to every fix days of the month; which is near cnough for common use: A copy of one of these tables for March 1784 is here inferted for the information of

Lusys	ι.	Day ocreaf.	١.	lelic			elio ng.		elio ng.			lelio			ç.		cho ng.		
1 3 1 9 2 5	3 4	35 59 23	16 16 17 17	ゅ	56 7	17 17 18 18	## T	 1	925	15	17 23 29 5			•	38	28	*	58 23 59 39	ł

"Now, as an example, we will suppose, that in order to fet the planets of the orrery, we want their heliocentric places for the 21ft of this month. Looking into the table, we take the 19th day, which is the nearest to the day wanted: then, accordingly we find the place of Saturn (b) is in 17° 17', or 17 degrees (rejecting the minutes, being in this case useless) of Capricornus (19); of Jupiter (24), in 18° of Aquarius (21); Mars (2), in 10° of Cancer (25); the earth (Θ), in 29° of Virgo (m); Venus (2), in 29° of Sagittarius (1); Mercury () in 28° of the fame fign; and in the fame manner for any other day therein specified. Upon even this circumstance depends a very pleasing allronomical praxis, by which the young tyro may at any time be able to entertain himself in a most rational and agreeable manner, viz. he may in a minute or two represent the true appearance of the planetary fyftem just as it really is in the heavens, and for any day he pleases, by affigning to each planet its proper place in its orbit; as in the following manner: For the 10th of March, as before, the place of Saturn is in 17° of Capricornus (17); now, laying hold of the arm of Saturn in the orrery, you place it over or against the 17° of Capricorn on the reliptic circle, conflantly placed on or furrounding the influment: thus doing the same for the other planets, they will have their proper heliocentric places for that day.

"Now in this fituation of the planets, we observe, that if a person was placed on the earth, he would see Venus and Jupiter in the fame line and place of the ecliptic, confequently in the heavens they would appear together, or in conjunction; Mcreury a little to the left or eastward of them, and nearer to the fun; Saturn to the right, or the westward, further from the

Sun; Mars directly opposite to detura to ther win Saturn appears in the west. Mars appears in the sec Saturn appears in the well. Many appears in the and vice verfa. Several other curious and encertainty particulars as depending on the above, may be said reprefented and flown by the leating particulars foregoing, when the which is turned, and all the nest fet into their respective motions, as We cannot close this detail properties more appearable than by the following account of an all the of that fort invented by the same of a Machanical Paradon, the which is adulted by means of what many, as he

which is actuated by means of what many, as he ferves, even good mechanics, would be ready to nounce impossible, viz. That the teeth of one when taking equally deep into the teeth of three others. should affect them in such a manner, that in turning it any way round its axis, it should turn one of them the fame way, another the contrary way, and the third

The folution of the paradox is given under the article MECHANICS; after which our author proceeds to give the following account of its uses. "This machine is so much of an orrery, as is sufficient to show the different lengths of days and nights, the viciffitudes of the feafons, the retrograde motion of the nodes of the moon's orbit, the direct motion of the apogeal point of her orbit, and the months in which the fun and moon must be celipsed.

" On the great immovcable plate A (see fig. 213.) are the months and days of the year; and the figns and degrees of the zodiac fo placed, that when the annual index h is brought to any given day of the year, it will point to the degree of the fign in which the fun is on that day. This index is fixt to the moveable frame

Aftrono- BC, and is carried round the immoveable plate with nical Ma- it, by means of the knob n. The carrying this frame chinery, and index round the immoveable plate, answers to the earth's annual motion round the fun, and to the fun's apparent motion round the ecliptic in a year.

"The central wheel D (being fixt on the axis a, which is fixt in the centre of the immoveable plate) turns the thick wheel E round its own axis by the motion of the frame; and the teeth of the which E take into the teeth of the three wheels F, G, H, whose axes turn within one another, like the axes of the hour, minute, and fecond hands of a clock or watch, where the records are shown from the centre of the dialplate.

" Oo the upper end of these axes, are the round plates I, K. L.; the plate I being on the axis of the wheel F, K on the axis of G, and L on the axis of H. So that, whichever way thefe wheels are affected, their respective plates, and what they support, must be affeeted in the same manner; each wheel and plate be-

ing independent of the others.

"The two upright wites M and N are fixed into the plate I; and they support the small coliptic OP, on which, in the machine, the figns and degrees of the ecliptic are marked. This plate also supports the small terrestrial globe c, on its inclining axis f, which is fixed into the plate near the foot of the wire N. This axis inclines 232 degrees from a right line, supposed to be perpendicular to the furface of the plate 1, and also to the plane of the small ecliptic OP, which is parallel to

the plane of the small ectiptic Or, which is parameted that plate.

To a the earth s in the ereform g which goes more with that way made the earth, and stands perpendicular to the plane of the latall ecliptic OP, directly size the size of the latall ecliptic OP, directly size the size the size from the other half.

It is the earth heart the sum from the other half.

It is the earth heart the sum from the other half.

It is the earth heart the sum from the other half.

It is the earth heart the sum of the represents the earth said darkness, and therefore ought into part the earth, but cannot in a machine, which is sum of the earth said which is supported to the earth of the earth said which is supported the proveable frame BC. the moveable frame BC.

In the plate K are fixed the two upright wires Q they support the moon's inclined orbit ST in handes, which are the two opposite points of the moon's orbit where it interfects the ecliptic OP. The afcending node is marked a, to which the descending node is opposite below e, but hid from view by the globe c. The half of Te of this orbit is on the north fide of the ecliptic OP, and the other half e S a is on the fouth fide of the ccliptic. The moon is not in this machine; but when the is in either of the nodes of her orbits in the heavens, she is then in the plane of the ecliptic: when she is at T in her orbit, she is in her greatest north latitude; and when she is at S, she is in her greatest fouth latitude.

"In the plate L is fixed the crooked wire UU, which points downward to the fmall ecliptic OP, and shows the motion of the moon's apogee there n, and

its place at any given time.

"The ball Z represents the sun, which is supported by the crooked wire XY fixt into the upper plate of the frame at X. A straight wire W proceeds from

the fun Z, and points always towards the centre of the Allronoearth e; but towards different points of its furface at mical Madifferent times of the year, on account of the obliquity chinery. of its axis, which keeps its parallelism during the earth's annual course round the fun Z; and therefore must incline sometimes toward the sun, at other times from him, and twice in the year neither toward nor fi " the fun, but fidewife to him. The wire W is Cal is the fular ray.

" As the annual index h shows the sun's place in the ecliptic for every day of the year, by turning the frame round the axis of the inmoveable plate A, according to the order of the months and ligns, the folar ray does the same in the small ecliptic OP: for an this ecliptic has no motion on its axis, its figns and degrees still keep parallel to those on the immoveable plate. At the same time, the nodes of the moon's orbit S I' (or points where it interfects the ecliptic OP) are moved backward, or contrary to the order of figns, at the rate of 197 degrees every Julian year; and the moon's apogeal wire UU is moved forward, or according to the order of the figus of the celeptic, nearly at the rate of 41 degrees every Julian year; the year being denoted by a revolution of the earth e round the fun Z; in which time the annual index b goes round the circles of months and figns on the immoveable plate A.

"Take hold of the knob n, and turn the frame round thereby; and in doing this, you will perceive that the north pole of the earth c is constantly before the crefcent g, in the enlightened part of the earth toward the fun, from the 20th of March to the 23d of Sertember; in the fouth pole all that time behind the crefcent in the dark; and from the 23d of September to the 20th of March, the north pole is constantly in the dark behind the crefcent, and the fouth pole in the light before it; which shows, that there is but one day and one night at each pole, in the whole year; and that when it is day at either pole, it is night at the

" From the 20th of March to the 23d of September, the days are longer than the nights in all those places of the northern hemisphere of the earth which revolve through the light and dark, and shorter in those of the fouthern hemitphere. From the 23d of September to the 20th of March the reverse.

"There are 24 meridian femicircles drawn on the globe, all meeting in its poles; and as one rotation or turn of the earth on its axis is performed in 24 hours, each of these meridians is an hour distant from the other, in every parallel of latitude. Therefore if you bring the annual index h to any given day of the year, on the immoveable plate, you may see how long the day then is at any place of the earth, by counting how many of these meridians are in the light, or before the creicent, in the parallel of latitude of that place; and this number being subtracted from 24 hours, will leave remaining the length of the night. And it you turn the earth round its axis, all those places will pass direcally under the point of the folir ray, which the fun passes vertically over on that day, because they are just as many degrees north or fouth of the equator as the tun's declination is then from the equinocial.

"At the two equinoxes, viz. on the 20th of March. and 23d of September, the fun is in the equinoctial,

pheres.

Aftrono- and confequently has no declination. On these days, mical Ma- the folar ray points directly toward the equator, the chinery. earth's poles lie under the inner edge of the crefcent, or houndary of light and darkness; and in every parallel of latitude there are 12 of the meridians or hour circles before the crefcent, and 12 behind it; which shows that the days and nights then are each 12 hours long at all places of the earth. And if the earth be turned round its axis, you will fee that all places on it go equally through the light and the dark hemif-

> "On the 21st of June, the whole space within the north polar circle is enlightened, which is 231 degrees from the pole, all around; because the earth's axis then inclines 23 5 degrees toward the fun: but the whole space within the fouth polar circle is in the dark; and the folar ray points toward the tropic of Cancer on the earth, which is 23+ degrees north from the equator. On the 20th of December the reverse happens, and the folar ray points toward the tropic of Capricorn, which is 231 degrees fouth from the equa-

"If you bring the annual index h to the beginning of January, and turn the moon's orbit ST by its supporting wires Q and R till the afcending node (marked &) comes to its place in the ecliptic OP, as found by an ephemeris, or by aftronomical tables, for the beginning of any given year; and then move the annual index by means of the knob n, till the index comes to any given day of the year afterward, the nodes will stand against their places in the coliptic on that day; and if you move on the index till either of the nodes comes directly against the point of the solar ray, the index will then be at the day of the year on which the fun is in conjunction with that node. At the times of those new moons, which happen within seventeen days of the conjunction of the fun with either of the nodes, the fun will be eclipfed; and at the times of those full moons, which happen within twelve days of either of these conjunctions, the moon will be eclipsed. Without these limits there can be no eclipses either of the sun or moon; because, in nature, the moon's latitude or declination from the ecliptic is too great for the moon's shadow to fall on any part of the earth, or for the earth's fhadow to touch the moon.

"Bring the annual index to the beginning of January, and fet the moon's apogeal wire UU to its place in the ecliptic for that time, as found by astronomical tables; then move the index forward to any given day of the year, and the wire will point on the small ecliptic to the place of the moon's apogee for that time.

"The earth's axis finclines always toward the beginning of the fign Cancer on the small eliptic OP. And if you set either of the moon's nodes, and her apogeal wire to the beginning of that fign, and turn the plate A about, until the earth's axis inclines toward any fide of the room (suppose the north fide), and then move the annual index round and round the immoveable plate A, according to the order of the months and figns upon it, you will fee that the carth's exis and beginning of Cancer will fill keep toward the sime fide of the room, without the least deviation from but the nodes of the moon's orbit ST will turn progressively towards all the sides of the room, con-

trary to the order of figns in the small ecliptic OP, Astronoor from east, by fouth, to west, and so on; and the mical Maapogeal wire UU will turn the contrary way to the chinery. motion of the nodes, or according to the order of the figns in the small ecliptic, from west, by south, to cast, and so on quite round. A clear proof that the wheel F, which governs the earth's axis and the small ecliptic, does not turn any way round its own centre; that the wheel G, which governs the moon's orbit OP, turns round its own centre backward, or contrary both to the motion of the frame BC and thick wheel E; and that the wheel H, which governs the moon's apogeal wire UU, turns round its own centre forward, or in direction both of the motion of the frame and of the thick wheel E, by which the three wheels F, G, and H, are affected.

"The wheels D, E, and F, have each 30 teeth in the machine; the wheel G has 37, and H 44.

"The parallelism of the earth's axis is perfect in this machine; the motion of the apogee very nearly fo; the motion of the nodes not quite fo near the truth, though they will not vary scanibly therefrom in one year. But they cannot be brought nearer unless larger wheels, with higher aumbers of teeth, are used.

In nature, the moon's apogee goes quite round the

ecliptic in 8 years and 312 days, in direction of the earth's annual motion; and the nodes go round the ecliptic, in a contrary direction, in 18 years and and

ecliptic, in a contrary direction, in 18 years and days. In the machine, the sporce root round the ecliptic OP in eight rease and four files of a year, and the nodes in eighteen years and the curious exchine shows the motion of the curious amoving round the root of the second round the contract of times, and may be so contract as a same times, and may be so contract as a same time, and what he is contract as a same time by the late Dr Delagation.

The dark eligitiest groupe name and their second round is the contract of the same second round and second round in the contract of the same second round is the same second round as a same second round round

of g bid f m is the or in the carried body in discrete of letters, by the sac on the were as it approximates acres ther from the fun, being needs. In the section a, and fartheil in the appealing. The was 5, 58 c, 68 d, &c. or comments of these sections. triangles, are all equal; and in every turn of the wind N, the comet Y is carried over one of their assess ! confequently, in as much time as it moves from f to g, or from g to h, it moves from m to a br from a to b; and fo of the reft, being quickeft of all me m, and flowest at g. Thus the comet's velocity in its orbit continually decreases from the perihelion a to the aphelion g; and increases in the same proportion from g

The elliptic orbit is divided into 12 equal parts or figns, with their respective degrees, and so is the circle on parstu, which represents a great circle in the heavens, and to which the comet's motion is referred by a small knob on the point of the wire W. Whillt the comet moves from f to g in its orbit, it appears to move only about five degrees in this circle, as is shown by the small knob on the end of the wire W; but in as short time as the comet moves from m to a, or from a to b, it appears to describe the large space t n or no in the heavens, either of which spaces con-

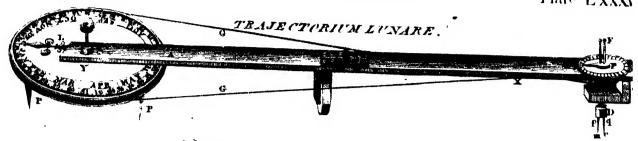

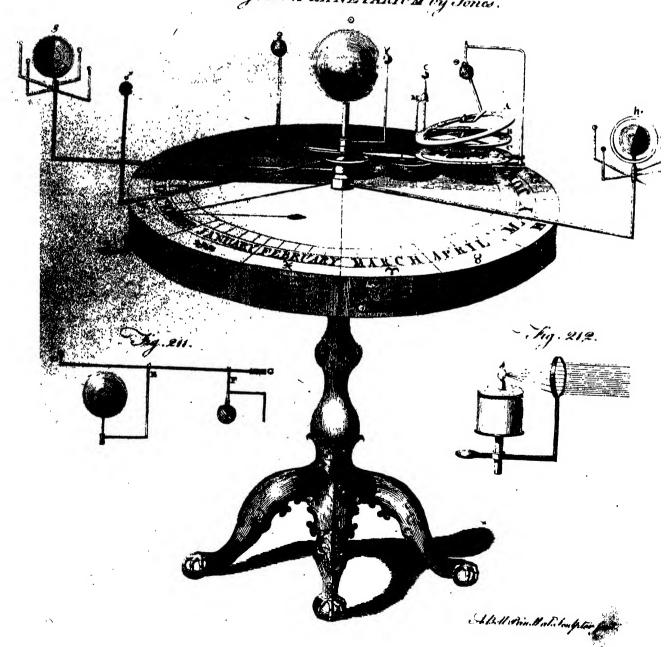

Fig 210. PLANETARIUM by Jones.

Adronomi- tains: 120 dogress, or four figns. Were the eccentricity cal Machi-of its orbit greater, the greater fill would be the differ-

ence of its motion, and vice verfa.

ABCDEFGHIKLM is a circular orbit for showing the equable motion of a body round the sun S, describing equal areas ASB, BSC, &c. in equal times with those of the body Y in its elliptical orbit above mentioned; but with this difference, that the circular motion describes the equal arcs AB, BC, &c. in the same equal times that the elliptical motion describes the unequal arcs, ab, bc, &c.

Now suppose the two bodies Y and 1 to start from the points a and A at the same moment of time, and, each having gone round its respective orbit, to arrive at these points again at the same instant, the body Y will be forwarder in its orbit than the body I all the way from a to g, and from A to G: but 1 will be forwarder than Y through all the other half of the orbit; and the difference is equal to the equation of the body Y in its orbit. At the points a A, and g G, that is, that in the peribelion and aphelion, they will be equal; and then the equation rapishes. This shows why the equation of a body moving in an elliptic orbit is added to the mean or supposed circular motion from the peribelion to the aphelion and fubtracted from the aphelion to the perihelion, in bodies moving round the fun, or from the parigee to the apogee, and from the apagee to the perigee in the moon's motion round the earth.

It is easy to see, that the end of b of the elliptical plate FF being farther from its axis E than the opposite end I is, must describe a circle so much the larger in proportion, and therefore move through so much more space in the same time; and for that reason the end b moves so much faster than the end I, although it goes no sooner round the centre E. But then the quick moving end b of the plate FF leads about the short end b K of the plate GG with the same velocity; and the slow-moving end I of the plate FF coming half round as to B, must then lead the long end b of the plate GG as slowly about: so that the elliptical plate FF and its axis E move uniformly and equally quick in every part of its revolution; but the elliptical

Vol. II. Part II.

plate GG, together with its axis K, must move very Astronomiunequally in different parts of its revolution; the difference being always inversely as the distance of any point of the circumference of GG from its axis at K: or in other words, to instance in two points, if the distance K k be four, sive, or six times as great as the distance K b, the point b will move in that position, four, sive, or six times as fast as the point k does, when the plate GG has gone half round; and so on for any other eccentricity or difference of the distances K k and K b. The tooth I on the plate FF falls in between the two teeth at k on the plate GG; by which means the revolution of the latter is so adjusted to that of the former, that they can never vary from one another.

On the top of the axis of the equally moving wheel D in fig. 217. is the fun S in fig. 216: which fun, by the wire fixed to it, carries the ball 1 round the circle ABCD, &c. with an equable motion, according to the order of the letters: and on the top of the axis K of the unequally moving ellipses GG, in fig. 218. is the sun S in fig. 217. carrying the ball Y unequally round in the elliptical groove abcd, &c. N. B. This elliptical groove must be precisely equal and similar to the verge of the plate GG, which is also equal to that of FF.

In this manner machines may be made to show the true motion of the moon about the earth, or of any planet about the sun, by making the elliptical plates of the same eccentricities, in proportion to the radius, as the orbits of the planets are, whose motions they represent; and so their different equations in different parts of their orbits may be made plain to sight, and elearer ideas of these motions and equations acquired in half an hour, than could be gained from reading half a day about such motions and equations.

The Improved Celestial Globe, fig. 187. On the north pole of the axis, above the hour circle, is fixed an arch MKH of 23 to degrees; and at the end H is fixed an upright pin HG, which stands directly over the north pole of the ecliptic, and perpendicular to that part of the surface of the globe. On this pin are two moveable collets at D and H, to which are fixed the quadrantile wires N and O, having two little balls on their ends for the fun and moon, as in the figure. The collet D is fixed to the circular plate F, whereon the 29 days of the moon's age are engraven, beginning just under the sun's wire N; and as this wire is moved round the globe, the plate F turns round with it. These wires are easily turned, if the Icrew G be flackened; and when they are fet to their proper places, the forew ferves to fix them there, so as in turning the ball of the globe, the wires with the fun and moon go round with it; and thefe two little balls rife and let at the same times, and on the same points of the horizon, for the day to which they are rectified, as the fun and moon do in the hea-

Because the moon keeps not her course in the ecliptic (as the sun appears to do), but has a declination of \$\frac{1}{2}\$ degrees on each side from it in every lunation, her ball may be screwed as many degrees to either side of the ecliptic as her latitude or declination from the ecliptic amounts to at any given time.

The horizon is supported by two semicircular arches, because pillars would stop the progress of the 4 E balls

402

Aftronomi- balls when they go below the horizon in an oblique ca Machi- fphere.

To redify this globe. Elevate the pole to the latitude of the place; then bring the fun's place in the ecliptic for the given day to the brazen meridian, and fet the hour index at 12 at noon, that is, to the upper 12 on the hour circle; keeping the globe in that fituation, flacken the ferew G, and fet the fun directly over his place on the meridian; which done fet the moon's wire under the number that expresses her age for that day on the plate F, and she will then stand over her place in the ecliptic, and show what constellation she is in. Laftly, Fasten the screw G, and adjust the moon to her latitude, and the globe will be rectified.

Having thus rectified the globe, turn it round, and observe on what points of the horizon the sun and moon balls rife and fet, for thefe agree with the points of the compass on which the sun and moon rife and fet in the heavens on the given day; and the hour index shows the times of their rising and fetting: and likewife the time of the moon's paffing over the meri-

494

This simple apparatus shows all the varieties that can happen in the rifing and fetting of the fun and moon; and makes the forementioned phenomena of the harvest moon plain to the eye. It is also very useful in reading lectures on the globes, because a large company can fee this fun and moon go round, rifing above and fetting below the horizon at different times, according to the feafons of the year; and making their appulfes to different fixed stars. But in the usual way, where there is only the places of the fun and moon in the ecliptic to keep the eye upon, they are eafly loft fight of,

unless they be covered with patches.

The Trajectorium Lunare, fig. 208. This machine is for delineating the paths of the earth and moon, showing what fort of curves they make in the ethereal regions. S is the fun, and E the earth, whose centres are 95 inches distant from each other; every inch answering to 1,000,000 of miles. M is the moon, whose centre is 24 parts of an inch from the earth's in this machine, this being in just proportion to the moon's distance from the earth. AA is a bar of wood, to be moved by hand round the axis g which is fixed in the wheel Y. The circumference of this wheel is to the circumference of the small wheel L (below the other end of the bar) as 365 days is to 29 to or as a year is to a lunation. The wheels are grooved round their edges, and in the grooves is the cat-gut firing GG croffing between the wheels at X. On the axis of the wheel L is the index F, in which is fixed the moon's axis M for carrying her round the earth E (fixed on the axis of the wheel L) in the time that the index goes round a circle of 291 equal parts, which are the days of the moon's age. The wheel Y has the months and days of the year all round its limb; and in the bar AA is fixed the index I, which points out the days of the months answering to the days of the moon's age, shown by the index F, in the circle of 201 equal parts at the other end of the bar. On the axis of the wheel L is put the piece D, below the cock C, in which this axis turns round; and in D are put the pencils e and m. directly under the earth E and moon M; fo that m is carried round e as M is round E.

Lay the machine on an even floor, prefling gently Aftronomion the wheel Y, to cause its spiked feet (of which two cal Machia appear at P and P, the third being supposed to be hid from fight by the wheel) enter a little into the floor to fecure the wheel from turning. Then lay a paper about four feet long under the pencils e and m, crosswife to the bar; which done, move the bar flowly round the axis g of the wheel Y; and as the earth E goes round the fun S, the moon M will go round the earth with a duly proportioned velocity; and the friction wheel W running on the floor, will keep the bar from bear, ing too heavily on the pencils e and m, which will delineate the paths of the earth and moon. As the index. I points out the days of the months, the index F flows the moon's age on these days, in the circle of 291 equal parts. And as this last index points to the different days in its circle, the like numerical figures may be fet to those parts of the curves of the earth's path and moon so where the pencils e and m are at those times respectively, to show the places of the earth and moon. If the pencil e be pushed a very little off, as if from the pencil m, to about to part of their difisnee, and the pencil as puthed as much towards e, tobring them to the same distances again, though not to the same points of space; then, as m goes round e, e will go as it were round the centre of granty be tween the earth e and moon my bot this motion will not fentibly after the figure of the earth's petit of the

moon's.

If a pin, as o, be put through the pine head towards that of the pin g is the head towards that of the pin g is the head will always keep anythe as or as the fame tide of the same of the earth. But the head will as an equatorial simulator of the point m, making at put the line of its progress, or the or the line of its progress, or the or the line of its progress, or the or the line of its progress. her axis.

SECT. XIII. A Dela price at the mical Informents by which Allinging mel accurate Observationes

By practical altronomy is implied the knowledge observing the celestial bodies with respect to their tion and time of the year, and of deducing from those oblervations certain conclusions useful in calculating the time when any proposed polition of these bodies shall

happen. For this purpole, it is necessary to have a room or place conveniently fituated, fuitably contrived, and furnished with proper astronomical instruments. It should have an uninterrupted view from the zenith down to (or even below) the horizon, at least towards its cardinal points; and for this purpole, that part of the roof which lies in the direction of the meridian in particular, should have moveable covers, which may easily be moved and put on again; by which means an instrument may be directed to any point of the heavens between the horizon and the zenith, as well to the northward as fouthward.

This place, called an Observatory, should contain fome, if not all, of the following inftruments.

I. A PENDULUM CLACK, for showing equal time.

Afronomi-

This should show time in hours, minutes, and seconds; eal Indru- and with which the observer, by hearing the beats of the pendulum, may count them by his ear, while his eye is employed on the motion of the celestial object he is observing. Just before the object arrives at the position described, the observer should look on the clock and remark the time, suppose it 9 hours 15 minutes 25 feconds; then faying, 25, 26, 27, 28, &c. responsive to the beat of the pendulum, till he fees through the instrument the object arrived at the position expected; which suppose to happen when he fays 38, he then writes down o h. 15 min. 38 sec. for the time of observation, annexing the year and the day of the month. If two persons are concerned in making the observation, one may read the time audibly while the other observes through the instrument, the observer repeating the last second read when the defired polition happens.

II. An Achromatic Refracting Telescore, or a reflecting one, of two feet at least in length, for observing particular phenomens. These inflruments

The Mural Deadrant is in the form of a quar-

set of a circle, contained under two radii at right to one another, and in such equal to one fourth the let of the circle of the sale of a flone or had and the sale of the circle of the circle of the sale of the sa ter of a circle, contained under two radii at right

a let mouth have blually been made from five rece regime, und the Bird, and other eminent materiatical inframent makers now in London. The contraction of them being generally the fame in all the fixes, we shall here describe one made by the Iste Ion. Silfon, under the direction of the late M. Graham. Fig. 214. reprefents the instrument as already fixed to the wall. It is of copper, and of about feet radius. The frame is formed of flat bars, and frengthened by edge bars affixed underneath perpendicularly to them. The radii HB, HA, being divided each into four equal parts, serve to find out the points D and E, by which the quadrant is freely fur spended on its props or iron supports that are fastened fecurely in the wall.

One of the Supports E is represented separately in e on one fide of the quedrant. It is moveable by means of a long slender rod EF or ef, which goes into a hollow screw in order to restore the instrument to its situation when it is discovered to be a little deranged. This may be known by the very fine perpendicular thread HA, which ought always to coincide with the same point A of the limb, and carefully examined

to be fo by a small magnifying telescope at every Astronomiobservation. In order to prevent the unfteadiness of cal inftrufo great a machine, there should be placed behind the menta. limb four copper ears with double cocks I, K, I, K. There are others along the radii HA and HB. Each of these cocks contains two screws, into which is fastened the ears that are fixed behind the qua-

Over the wall or stone which supports the instrument, and at the same height as the centre, is placed horizontally the axis PO, which is perpendicular to the plane of the instrument, and which would pass through the centre if it was continued. This axis turns on two pivots P. On this axis is fixed at right angles another branch ON, loaded at its extremity with a weight N capable of equipoifing with its weight that of the telescope LM; whilst the axis, by its extremity nearest the quadrant, carries the wooden frame PRM, which is fastened to the telescope in M. The counterpoile takes off from the observer the weight of the telescope when he raises it, and hinders him from either forcing or straining the instrument.

The lower extremity (V) of the telescope is furnished with two small wheels, which take the limb of the quadrant on its two fides. The telescope hardly bears any more upon the limb than the small friction of thefe two wheels; which renders its motion fo extremely easy and pleasant, that by giving it with the hand only a small motion, the telescope will run of itfelf over a great part of the limb, balanced by the

counterpoise N.

When the telescope is to be stopped at a certain pofition, the copper hand T is to be made use of, which embraces the limb and springs at the bottom. It is fixed by fetting a ferew, which fastens it to the limb. Then, in turning the regulating ferew, the telescope will be advanced; which is continued until the flar or other object whose altitude is observing be on the horizontal fine thread in the telescope. Then on the plate X supporting the telescope, and carrying a vernier or nonius, will be feen the number of degrees and minutes, and even quarters of minutes, that the angular height of the object observed is equal to. The remainder is eafily estimated within two or three seconds

There are several methods of subdividing the divifions of a mural quadrant, which are usually from five to ten minutes each; but that which is most commonly adopted is by the vernier or nonius, the contrivance of Peter Vernier a Frenchman. This vernier confilts of a piece of copper or brafa, CDAB (fig. 215.), which is a imail portion of X (fig. 214.) represented feparately. The length CD is divided into 20 equal parts, and placed contiguously on a portion of the division of the limb of the quadrant containing 21 divisions, and thereby dividing this length into 20 equal parts. Thus the first division of the vernier piece marked 15, beginning at the point D, is a little matter backward, or to the left of the first division of the limb, equal to 15. The second division of the vernier is to the left of the fecond division of the limb double of the first difference, or 30"; and fo on unto the twentieth and last division on the left of the vernier piece; where the 20 differences being accumulated each of the twentieth part of the division of the limb, this last division will

498

Afternoons he found to agree exactly with the 21st division on the

cal liftru-flimb of the quadrant.

The index must be pushed the 20th part of a divifion, or 15", to the right; for to make the second diwifton on the vernier coincide with one of the divisions of the limb, in like manner is moving two 20ths, or 30', we must look at the second division of the index, and there will be a coincidence with a division of the limb. Thus may be conceived that the beginning D of the vernier, which is always the line of reckoning, has advanced two divitions, or 30", to the right, when the second division, marked 30 on the vernier, is seen to correspond exactly with one of the lines of the qua-

By means of this vernier may be readily diffusguished the exactitude of 15" of the limb of a quadrant five feet radius, and fimply divided into 5 .. By an estimation by the eye, afterwards the accuracy of two or three fecouds may be eafily judged. On the fide of the quadrant is placed the plate of copper which carrice the telescope. This plate carries two verniers. The outer line CD divides five minutes into 20 parts, or 15" each. The interior line A B answers to the parts of another division not having 90°, but 96 parts of the quadrant. It is usually adopted by English astronomers on account of the facility of its subdivisions. Each of the 96 portions of the quadrant is equivalent to 56' 15" of the usual divisions. It is divided on the limb into 16 sparts, and the arch of the vernier AB contains 25 of these divisions; and being divided itself into 24, immediately gives parts, the value of each of which is 8" 47\frac{1}{3}". From this mode a table of reduction may easily be constructed, which will serve to find the value of this second mode of dividing in degrees, minutes, and seconds, reckoning in the usual manner, and to have even the advantage of two different modes; which makes an excellent verification of the divisions on the limb of the quadrant and observed heights by the vernier.

2. The Portable Astronomical Quadrant, is that in firstment of all others which aftronomers make the greatest use of, and have the most esteem for. They are generally made from 12 to 23 inches. Fig. 219. is a representation of the improved modern one as made by the late Mr Sisson, and by the present mathematical instrument makers. This is capable of being carried to any part of the world, and put up for observations in an easy and accurate manner. It is made of brafts. and strongly framed together by crossed perpendicular The arch AC, and telescope EF, are disided. and constructed in a fimilar manner to the mural quadrant, but generally without the division of 96 parts. The counterpoile to the telescope T is represented at P; and also another counterpoile to the quadrant itself: at P. The quadrant is fixed to a long axis, which goes into the pillar KR. Upon this axis is fixed an index, which points to and fubdivides by a vernier the divisions of the azimuth circle K. This azimuth circle is extremely useful for taking the azimuth of a destial body at the same time its altitude is observed. The upper end of the axis is firmly connected with the adjusting frame GH; and the pillar is supported on the eroffed feet at the bottom of the pillar KR with the adjusting screws a, b, a, d.

When this inframent is let up for ule or obleves.

tion, it is necessary that two adjustments be very accu- Afternami rately made: One, that the plane or furface of the in- cal infirme ftrument be truly perpendicular to the horizon; the other, that the line improfed to be drawn from the centre to the first line of the limb, be truly on a level or parallel with the horizon. The first of these particulars is done by means of the thread and plummet p; the thread of which is usually of very fine filver wire, and it is placed opposite to a mark made upon the end of the limb of the instrument. The four ferews at the foot, a, b, c, d, are to be turned until a perfect coincidence is observed of the thread upon the mank, which is accurately observed by means of a small telefcope T, that fits on the limb. The other adjustment is effected by means of the spirit level I., which applies on the frame GH, and the small forewe turned as before until the bubble of air in the level fettles in the middle of the tube. The dotted tube EB is a kind of prover to the inframent; for by observing at what mark the centre of it appears againft, or by putting up a mark against it is will at any time discount if the inframent has been displaced. The force S, at the index, is the regulating or adjusting force, to move the telescope and index, the obtainment.

the rides, a tra regarded there there objects are more the telefope and lakes, thereby.

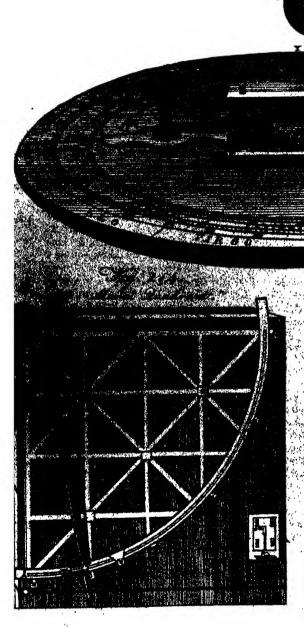

We describe the fact of independent and describe the formal sections of the different and declinations between appropriate the different fact of which is too great to be able and it the proposetor. It was the inventors of the last ingrenture Mr. Consent Graham, B. B. and its considerable the rice follows particulars. Let A.I. fait in a postulation were followed a frong plane (I.I. fait) and a section of the last in a section of the area at II. I set the more than a section in the area at II. I set the more than a section in the section of th to another, it is easy to more the festion shout the P, into fuch a polition, that the arch AB, when ed. Mill take in both the flore in their pullage, byth plane of its provided the difference of their declina tions does not exceed the erch AB. Then, her fixed the plane of the fector a little to the wellward of both the flare, move the telescope CR by the laying G; and abserve by a clock the time of each traplet over the cush hairs, and allo the degrees and minute upon the and AB, out by the index at each transit ; then in the difference of the arches, the difference of the declinations, and by the difference of the times. we have the difference of the right alcentions of the

The dimensions of this instrument are these: The length of the telescope, or the radius of the sector, is 21 feet; the breadth of the radius, near the end C. is 14 inch; and at the end D two inches. The breadth of the limb AB is 14 lock; and its length

Astronomi- fix inches, containing ten degrees divided into quarters, cal Instru- and numbered from either end to the other. The telements fcope carries a nonius or fubdividing plate, whose length, being equal to fixteen quarters of a degree, is divided into fifteen equal parts; which, in effect, divides the limb into minutes, and, by estimation, into smaller parts. The length of the square axis HIF is eighteen inches, and of the part HI twelve inches; and its thickness is about a quarter of an inch: the diameters of the circles are each five inches; the thickness of the plates, and the other measures, may be taken at the direction of a workman.

This instrument may be rectified, for making observations, in this manner: By placing the interlection of the crofs hairs at the fame diffance from the plane of the fector, as the centre of the object glass, the plane described by the line of fight, during the circular motion of the telescope upon the limb, will be sufficiently true, or free from conical curvity; which may be exar mined by fulpending a long plumh-line at a convenient diffance from the inflrument; and by fixing the plane of the sector in a vertical position, and then by observing, while the telescope is moved by the forew along the limb, whether the cross hairs appear to move along

the plumb-line.

The axis b f q may be elevated nearly parallel to the axis of the earth, by means of a small common quadrant; and its error may be corrected, by making the line of fight follow the circular motion of any of the circumpolar stars, while the whole instrument is moved about its axis h fine the telescope being fixed to the limb; for this purpole, let the teleleope k / be directad to the flan a when it palles over the highest point til its diurnal circle, and let the division cut by the namius be then noted a then, after twelve hours, when the flar comes to the lowest point of its circle, having turned the inftrument half round its axis, to bring the relescope into the polition on n; if the cross, hairs cover the fame flar supposed at b, the elevation of the axis the exactly right; but if it be necessary to move the telescope into the position us, in order to point to this flar at c, the such m w, which measures the angle af a or bfc, will be known; and then the axis bf a mult be depressed half the quantity of this given angle if the ftar passed below b, or must be raised so much higher if above it; and then the trial must be repeated till the true elevation of the axis he obtained. By making the like observations upon the same star on each fide the pole, in the fix o'clock hour circle, the error of the axis toward the cast or west, may also be found and corrected, till the cross hairs follow the star quite round the pole; for supposing a o p.b c to be an arch of the meridian (or in the second practice of the fix o'clock hour circle), make the angle a f p equal to half the angle afc, and the line fp will point to the pole; and the angle of p, which is the error of the axis, will be equal to half the angle bfc, or mfu, found by the observation; because the difference of the two angles afb, afc, is double the difference of their halves a fo. and a fp. Unless the star be very near the pole, allowance must be made for refractions.

VI, TRANSIT and Equal Altitune Infruments. 1. The Transit Instrument is used for observing objects as they pals oven the meridian. It confifts of a telescope fixed at right angles to an horizontal axis; which axis must be so supported that what is Astronomicalled the line of collimation, or line of fight of the te- cal Inflatelescope, may move in the plane of the meridian. This nients. instrument was first made by the celebrated Mr Roemer in the year 1689, and has fince received great improvements. It is made of various fizes, and of large dimenfions in our great observatories; but the following is one of a fize sufficiently large and accurate for all the uleful purpofes.

The axis AB (fig. 220.), to which the middle of the telescope is fixed, is about 27 feet long, tapering gradually toward its ends, which terminate in cylinders well turned and impothed. The telescope CD. which is about four feet and 11 inch diameter, is connected with the axis by means of a strong cube or die G, and in which the two cones MQ, forming the axis, are fixed. This cube or flock G ferves as the principal part of the whole machine. It not only keeps together the two cones, but holds the two fockets KH, of 15 inches length, for the two telescopic tubes. Each of these sockets has a square base, and is fixed to the cube by four ferews. These fockets are cut down in the fides about eight inches, to admit more easily the tube of the telescope; but when the tube is inferted, it is kept in firm by fcrewing up the tightening screws at the end of the sockets at K and Thefe two fockets are very useful in keeping the telescope in its greatest possible degree of steadings. They also afford a better opportunity of balancing the telescope and reclifying its vertical thread, than by any other means.

In order to direct the telescope to the given height that a star would be observed at, there is fixed a semicircle AN on one of the supporters, of about 8; inches diameter, and divided into degrees. The index is fixed on the axis, at the end of which is a vernier, which subdivides the degrees into 12 parts, or five minutes. The index is moveable on the axis, and may be closely applied to the divisions by means of a tight-

ening fcrew.

Two upright posts of wood or stone YY, firmly fixed at a proper distance, are to sustain the supporters of this instrument. These supporters are two thick brafs plates RR, having well smoothed angular notches in their upper ends, to receive the cylindrical arms of the axis. Each of these notched plates 13 contrived to be moveable by a forew, which flides them upon the surfaces of two other plates immoveably fixed upon the two upright pillars; one plate moving in a horizontal, and the other in a vertical direction; or, which is more fimple, these two modes are sometimes applied only on one fide, as at V and P, the horizontal motion by the screw P, and the vertical by the ferew V. These two motions serve to adjust the telescope to the planes of the horizon and meridian: to the plane of the horizon by the spirit level EF, hung by DC on the axis MQ, in a parallel direction: and to the plane of the meridian in the following man-

Observe by the clock when a circumpolar star scen through this instrument transits, both above and below the pole; and if the times of describing the eastern and western parts of its circuit are equal, the telescope is then in the plane of the meridian: otherwise the forew I must be gently turned that it may move the tele-

ICZ

5 < 3

Astronomi-scope io much that the time of the star's revolution be cal Infirm- bifected by both the upper and lower transits, taking care at the fame time that the axis remains perfectly horizontal. When the telescope is thus adjusted, a mark must be set at a considerable distance (the greater the better) in the horizontal direction of the interrection of the crofs wires, and in a place where it can be illuminated in the night-time by a lanthorn hanging near it; which mark being on a fixed object, will scive at all times afterwards to examine the position of the telescope by, the axis of the inftrument being first adjusted by means of the level.

To adjust the Clock by the Sun's Transit over the Meridian. Note the times by the clock when the preceding and following edges of the fun's limb touch the crofs wires. The difference between the middle time and 12 hours, shows how much the mean, or time by the clock, is fafter or flower than the apparent, or for lar time, for that day: to which the equation of time being applied, will show the time of mean noon for

that day, by which the clock may be adjusted.

2. The Equal Altitude Instrument is an instrument that is used to observe a celestial object when it has the fame altitude on both the east and well fides of the meridian, or in the morning and afternoon. It principally confills of a telescope about 30 inches long fixed to a fextantal or femicircular divided arch; the centre of which is fixed to a long vertical axis: but the particulars of this inftrement the reader will fee explain-

ed in Ortics, Part III.

3. Compound Transit Instrument. Some instruments have been contrived to answer both kinds of observations, viz. either a transit or equal altitudes. Fig. 222. represents such an instrument, made first of all for Mr Le Monnier the French astronomer by the late Mr Siffon, under the direction of Mr Opaham, mounted

and fixed up ready for observation.

AB is a telescope, which may be 3, 4, 5, or 6 feet long, whole cylindrical tube fits exactly into another hollow cylinder a b, perpendicular to the axis: thefe leveral pieces are of the best hammered plate brafs. The cylindrical extremity of this axis MN are of folid bell-metal, and wrought exquifitely true, and exactly the same size in a lathe; and it is on the pertection to which the cylinders or trunnions are turned that the juffness of the instrument depends. In the common focus of the object-glass and eye-glass is placed a reticle (fig. 223.), confilling of three horizontal and parallel fine stretched filver wires, fixed by pins or terews to a brafs circle, the middle one passing through its centre, with a fourth vertical wire likewife paffing through the centre, exactly perpendicular to the former three.

The horizontal axis MN (fig. 222.) is placed on a flrong brafs frame, into the middle of which a fteel cylinder GH is fixed perpendicularly, being turned truly round, and terminating in a conical point at its lower extremity; where it is let into a finall hole drilled in the middle of the dove-tail flider; which flider is Supported by a hollow tube fixed to the supporting piece IK, confishing of two strong plates of brais, foined together at right angles, to which are fixed two fron cramps L., L., by which it is fastened to the stone wall of a fouth window.

The upper part G of the steel spindle is embraced by

a collar def, being in contact with the blunt extre-Aftronomie mity of three fcrews, whose particular use will be ex- cal inflruplained by and by. O is another cylindrical collar ments. closely embracing the fleel spindle at about a third put of its length from the top; by the means of a small ferew it may be loofened or purched clote as occasion requires. From the bottom of this collar proceeds an arm or lever acted upon by the two ferews g h, whereby the whole influment, excepting the supporting piece, may be moved laterally, so that the telescope may be made to point at a diffant mark fixed in the vertical of the meridian. ik is a graduated femicircle of thin brafs forewed to the telescope, whereby it may be elevated to as to point to a known celeftial object in the day-time. Im is a spirit level parallel to the axis of rotation on the telefcope, on which two trunnions hang by two hooks at M and N. Along the upper side of the glass tube of the level sides a pointer to be fet to the end of the air bubble; and when the position of the axis of rotation is so adjusted by the screws that the air bubble keeps to the pointer for a whole revolution of the inftrument, the spindle GH is certainly perpendicular to the horizon, and then the line of collimation of the telescope describes a circle of equal altitude in the heavens. When the level is fuspended on the axis, raise or depress the tube of the level by twifting the neb of the screw n till you bring either end of the air bubble to rest at any point towards the middle of the tube, to which flide the index; then lift off the level, and, turning the ends of it contrariwite, hang to again on the trunnions; and if the air bubble refts exactly again, the index as before, the axis of rotation is truly horizontal: If not depreis that end of the axis which her on the same her of the pointer as the babble dbess by turning the neb of the screw at Na till the boothe returns about halfway towards the pointer of then having moved the pointer to the place where it now relie, invert the ends of the level again, and repeat the fame practice till the bubble refts exactly at the pointer in both policions of the level. If, after the telescope is turned uphile down, that is, after the trumions are inserted end four end, you perceive that the same points of a remore fixed object is covered by the vertical wire in the focus of the telescope, that was covered by it before the inversion, it is certain that the line of fight or collimation is perpendicular to the transverse axis: but if the faid vertical wire covers any other point, the braft circle that carries the hairs must be moved by a ferewkey introduced through the perforation in the fide of the tube at X, till it appears to bifect the line joining thefe two points, as near as you can judge; then, by reverting the axis to its former position, you will find whether the wires be exactly adjusted. N. B. The ball o is a counterpoile to the centre of gravity of the femicircle ik, without which the telescope would not rest in an oblique elevation without being fixed by a fcrew or fome other contrivance.

The feveral beforementioned verifications being accomplified, if the telefcope be elevated to any angle with the horizon, and there stopped, all fixed stars which pass over the three horizontal wires of the reticle on the eastern fide of the meridian in ascending, will have precifely the fame altitudes when in descending they again cross the same respective wires on the

504

ultioromi- west side, and the middle between the times of each al Inftru- respective equal altitude will be the exact moment of the ftar's culminating or passing the meridian. By the help of a good pendulum clock, the hour of their true meridional transits will be known, and consequently the difference of right afcention of different flars. Now, fince it will be fufficient to observe a star which has north declination two or three hours before and after its passing the meridian, in order to deduce the time of its arrival at that encle; it follows, that having once found the difference of right afcention of two flars about 60 degrees afunder, and you again observe the first of these fland at the same altitude both in the east and well fide, you inter with certainty the moment by the clock at which the second star will be on the meridian that same might, and by this means the transit inflrument may be fixed in the true plane of the meridian till the next day; when, by depressing it to some distant land objects, a mark may be discovered whereby it may ever after be rectified very readily, fo-as to take the transits of any of the heavenly bodies to great exactness, whether by night or day.

When such a mark is thus found, the telescope being directed carefully to it, must be fixed in that pofition by pinching fall the end of the arm or lever between the two opposite screws g b; and if at any future time, whether from the effect of heat or cold on the wall to which the inftrument is fixed, or by any

fettling of the wall itself, the mark appears no longer Astronomiwell bisected by the vertical wire, the telescope may cal Instrueafily be made to bifect it again, by giving a finall ments. motion to the pinching ferews.

The transit instrument is now considered as one of the most essential particulars of the apparatus of an

astronomical observatory.

Be fides the above may be mentioned

The Equatorial or Portable Observatory; an instrument defigned to answer a number of ulcful purpofes in practical aftronomy, independent of any particular oblervatory. It may be made use of in any steady room or place, and performs most of the useful problems in the science. The following is a description of one lately invented by Mr Ramfden, from whom it has received the name of the Univerful Equatorial.

The principal parts of this instrument (11g. 221.) are, 1. The azimuth or horizontal circle A, which reprefents the horizon of the place, and moves on a long axis B, called the vertical axis. 2. The equatorial or hour circle C, representing the equator, placed at right angles to the polar axis D, or the axis of the earth, upon which it moves. 3. The femicircle of declination E, on which the telefcope is placed, and moving on the axis of declination, or the axis of motion of the line of collimation F. These circles are meatured and divided as in the following table:

Mensures of the several circles and divisions on them.	Radius. In dec.		Limb divided to	Nonrus of 30 gives leconds.	Divided on limb lists parts of inc	Divided by Nonus ato parts of in	
Animuth or horizontal circle Equatorial or hour circle Vertical femicircle for declination or latitude.	5 5	f I 5	15' { 15' 1' in time	30" 30" 2"} 30"	45th 45th 42d	1350th 1350th 1260th	

The telescope, which is an achromatic refractorinches, and aperture 2.45 inches, and furnished with The different eye-tubes; to that its magnifying powers extend from 44 to 168. The telescope in this equatorial may be brought parallel to the polar axis, as in the figure, fo as to point to the pole star in any part of its diurnal revolution; and thus it has been obserwed near noon, when the fun has shone very bright. 5. The apparatus for correcting the error in altitude occasioned by refraction, which is applied to the eyeend of the telescope, and confitts of a slide G moving in a groove or dove-tail, and carrying the feveral eyetubes of the telescope, on which slide there is an index corresponding to five small divisions engraved on the dove-tail; a very small circle, called the refraction circle H, moveable by a finger ferew at the extremity of the eye-end of the telescope; which circle is diwided into half minutes, one entire revolution of it being equal to 3' 18', and by its motion mifes the centre of the crofs hairs on a circle of altitude; and likewife a quadrant I of 1; inch radius, with divisions on each fide, one expressing the degree of altitude of the object viewed, and the other expressing the minutes and se-

conds of error occasioned by refraction, corresponding to that degree of altitude: to this quadrant is joined a small round level K, which is adjusted partly by the pinion that turns the whole of this apparatus, and partly by the index of the quadrant; for which purpose the refraction circle is set to the same minute, &c. which the index points to on the limb of the quadrant; and if the minute, &c. given by the quadrant exceed the 3' 18" contained in one entire revolution of the refraction circle, this must be set to the excels above one or more of its entire revolutions; then the centre of the crofs hairs will appear to be raifed on a circle of altitude to the additional height which the error of refraction will occasion at that altitude.

This instrument stands on three feet I, distant from each other 14,4 inches; and when all the parts are horizontal is about 29 inches high: the weight of the equatorial and apparatus is only 59 lb. avoirdupois, which are contained in a mahogany cafe weighing

The principal adjustment in this instrument is that of making the line of collimation to describe a portion, of an hour circle in the heavens; in order to which, the azimuth circle must be truly level, the line of col-

Aftrenomi-limation or some corresponding line represented by cal inftru- the small brass roll M parallel to it, must be perpendicular to the axis of its own proper motion; and this last axis must be perpendicular to the polar axis: on the brafs rod M there is occasionally placed a hanging level N, the use of which will appear in the following

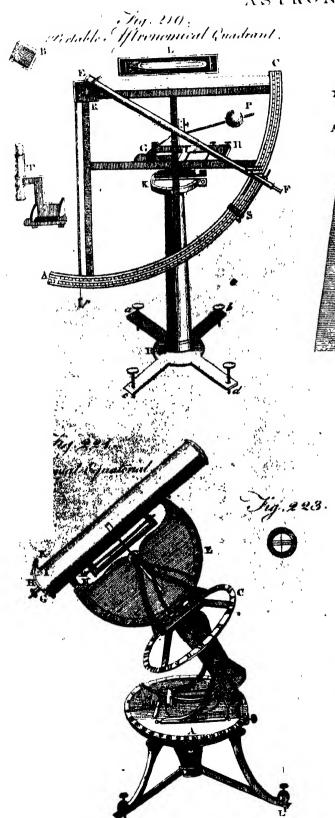

adjustments: The azimuth-circle may be made level by turning the inftrument till one of the levels is parallel to an imaginary line joining two of the feet forews; then adjust that level with these two feet serews; turn the circle half round, i. e. 180°; and if the bubble be not then right, correct half the error by the screw belonging to the level, and the other half error by the two foot forews: repeat this till the bubble comes right; then turn the circle 90° from the two former politions, and fet the bubble right, if it be wrong, by the foot ferew at the end of the level; when this is done, adjust the other level by its own fcrew, and the azimuth circle will be truly level. The hanging level must then be fixed to the brass rod by two hooks of equal length, and made truly parallel to it: for this purpose make the polar axis perpendicular or nearly perpendicular to the horizon; then adjust the level by the pinion of the declination semicircle; reverse the level, and if it be wrong, correct half the error by a small steel screw that lies under one end of the level, and the other half error by the pinion of the declination femicircle; repeat this till the bubble be right in both positions. In order to make the brafs rod on which the level is fuspended at right angles to the axis of motion of the telescope or line of collimation, make the polar axis horizontal, or nearly fo: fet the declination femicircle to oo, turn the hour circle till the bubble comes right; then turn the declination circle to 90°; adjust the bubble by raifing or depressing the polar axis (first by hand till it be nearly right, afterwards tighten with an ivory key the focket which runs on the arch with the polar axis, and then apply the same ivory key to the adjusting forew at the end of the faid arch till the bubble comes quite right); then turn the declination. circle to the opposite 900; if the level be not then right, correct half the error by the aforefaid adjusting ferew at the end of the arch, and the other half error by the two screws which raise or depress the end of the brais rod. The polar exis remaining inearly horizontal as before, and the declination-femicircle at 60, adjust the bubble by the hour circle; then turn the declination semicirole to 90°, and adjust the bubble by raifing or depressing the polar axis; then turn the hour circle 12 hours; and if the bubble be wrong, correct half the error by the polar axis, and the other half error by the two pair of capitan screws at the feet of the two supports on one side of the axis of motion of the telescope; and thus this axis will be at right angles to the polar axis. The next adjustment is to make the centre of cross hairs remain on the same object, while you turn the eye hibe quite round by the pinion of the refraction apparatus: for this adjustment, let the index on the flide to the first division on the dove-tail; and fet the division marked 18" on the refraction circle to its index; then look through the plescope, and with the pinion turn the eye-tube quite found; and if the centre of the hairs does not remain the same spot during that revolution, it must be

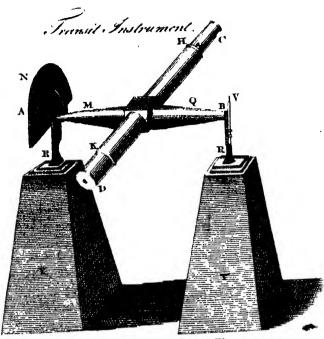

corrected by the four small screws, two and two at a Astronomitime (which you will find upon unfcrewing the nearest cal inftruend of the eye-tube that contains the first eye-glass); repeat this correction till the centre of the hairs remains on the spot you are looking at during an entire revolution. In order to make the line of collimation parallel to the brafs rod on which the level hangs, fet the polar axis horizontal, and the declination circle to 90°, adjust the level by the polar axis; look through the telescope on some distant horizontal object, covered by the centre of the crofs hairs; then invert the telescope, which is done by turning the hour circle half round; and if the centre of the crofs hairs does not cover the same object as before, correct half the error by the uppermost and lowermost of the four small fcrews at the eye-end of the large tube of the telefcope; this correction will give a fecond object now covered by the centre of the hairs, which must be adopted instead of the first object; then invert the telescope as before; and if the second object be not covered by the centre of the hairs, correct half the error by the fame two forews which were used before: this correction will give a third object, now covered by the centre of the hairs, which must be adopted instead of the fecond object; repeat this operation till no error remains: then let the hour circle exactly to 12 hours (the declination circle remaining at 90" as before); and if the centre of the crofs hairs does not cover the last object fixed on, fet it to that object by the two remaining fmall forews at the eye-end of the large tube, and then the line of collimation will be parallel to the brais rod. For rectifying the nonius of the declination and equatotal circles, lower the telefcope as many degrees, minutes, and feconds, below of or E on the declination semicircle as are equal to the complement of the latitude , then elevate the polar-axis till the bubble be horizontal, and thus the equatorial circle will be clevated to the colatitude of the place; fet this circle to 6 hours ; adjust the level by the pinion of the deelination circle; then turn the equatorial circle exactly to hours from the left position; and if the level he and right, correct one half of the error by the equatorial circle, and the other half by the declination circles then turn the equatorial circle back again exactly is hours from the last position; and if the level be still wrong, repeat the correction as before till it be right, when turned to either polition; that being done, let the noning of the equatorial circle exactly to 6 hours.

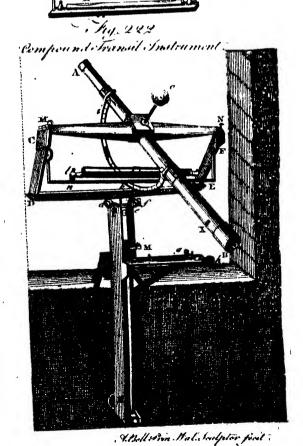

The principal uses of this equatorial are,

and the nonius of the declination circle exactly to oo.

1. To find your meridian by one observation only: for this purpole, elevate the equatorial circle to the colatitude of the place, and let the declination femicricle to the fun's declination for the day and hour of the day required; then move the azimuth and hour circles both at the fame time, either in the fame or contrary direction, till you bring the centre of the cross hairs in the telescope exactly to cover the centre of the fun; when that is done, the index of the hour circle will give the apparent or folar time at the inflant of observation; and thus the time is gained, though the fun be at a distance from the meridian; then turn the hour circle till the index points precifely at 12 o'clock, and lower the telescope to the horizon, in order to observe some point there

in the centre of your glass, and that point is your meridian mork found by one observation only; the best tunn for this operation is three hours before or three hours after 12 at noon.

2, to point the telefcope on a flw, though not on the meridian, in full day-light. Having elevated the equatorial circle to the co-latitude of the place, and fet the declination-femicircle to the flars declination, move the index of the hour circle till it shall point to the precise time at which the star is then distant from the meridian, found in tables of the right ascension of the stars, and the star will then appear in the glass. Besides these uses peculiar to this instrument, it is also applicable to all the purposes to which the principal astronomical instruments, viz. a transit, a quadrant, and an equal altitude instrument, are applied.

AST

Astrope
Wells

Astruc.

ASTROPE wells, near Banbury in Oxfordsaire, are recommended as excellent in female obstructions, the gravel, hypocondriac, and similar disorders. The water is a brisk, spirituous, pleasant-tasked chalybeate, and is also gently purgative. It should be drank from three to five quarts in the forenoon.

ASTROSCOPE, a kind of astronomical instrument, composed of two cones, on whose surface the constellations, with their stars, are delineated, by means, whereof the stars may easily be known. The astroscope is the invention of William Schuckhard, formerly asofessor of mathematics at Tubingen, who published a treatise expressly on it in 1698.

ASTRUC (John), a celebrated physician born in the year 1684, at the little town of Saron, in the province of Languedoc. His father, Protestant clergyman, bestowed particular mains and the earliest part of his education. After which he went to the university of Montpelier, where he was created mafter of arts in the year 1700. He then began the fludy of medicine; and, in two years, obtained the degree of bachelor, having upon that eccasion written a differtation on the cause of ferments. tion, which he defended in a very spirited manner. On the 25th of January 1703 he was created doctor of 4: physic; after which, before arriving at extensive practice, he applied to the study of medical authors, both ancient and modern, with uncommon affiduity. The good effects of his fludy foon appeared; for, in the year 1710, he published a treatife concerning muscular motion, from which he acquired very high reputation. In the year 1717, he was appointed to teach medicine at Montpelier; which he did with fuch perspicuity and eloquence, that it was univerfally faid he had been born to be a professor. His fame soon rose to such a height, that the king affigned him an annual falary: and he was, at the same time, appointed to superintend the mineral waters in the province of Languedoc. But as Montpelier did not afford sufficient scope for his

ASTURIA, an ancient kingdom of Spain, lubertants of this country, along with those of Camparing afferted their liberty long after the rest of Spain and received the Roman yoke. So great was their desire of liberty, that, after being closely shut up by the Roman asmy, they endured the most terrible calaminies of samine, even to the devouring of one another, rather than submit to the enemy. At length, however, the Asturians were for surrendering: but the Cantahrians opposed this measure, maintaining that they ought all to die sword in hand like brave men. Upon this the two nations quarrelled, notwithstanding their desperate situation; and a battle ensuing, 10,000 of the Asturians were driven to the intrenchments of the Romans,

the the 18th of May 1766, in the Bad 4

Afturiaswhom they begged in the most moving manner to re-Aylum. the emperor's fon-un-law refuting to admit them into the camp, some of these unhappy people put an end to their lives by falling upon their own fwords; others lighting great fires threw themselves into them, while fome poisoned themselves by drinking the juice of a venomous herb.

The campaign being put an end to by winter, the next year the Asturians summoned all their strength and refolution against the Romans; but notwithanding their utmost efforts of valour and despair, they were entirely defeated in a most bloody battle which lasted two days, and for that time entirely subdued. A few years afterwards they rebelled, in conjunction with the Cantabrians; but were foon reduced by the Romans, who madacred most of the young men that were capable of bearing arms. This did not prevent them from revolting anew in a short time afterwards; but without fuccefs, being obliged to submit to the Roman power, till the subversion of that empire by the Goths.

Asturias, anciently the kingdom of Asturia, is now a principality of modern Spain, bounded by Bifcay on the east, Galicia on the west, Castile and Old Leon on the fouth, and the fea on the north. Its greatest length is about 1 to miles, and its breadth 54. On the fouth it is separated from Castile and Old Leon by high mountains covered with woods. The province is tolerably fertile, but thiply inhabited. The inhabitakte value themselves miss in being descended from the ancient Goths. Even the poor peasants, who are fainted go to seek work in other provinces, call themselves Mustrious Goths and Mountaineers, thinking it felves illestrious Gothe and Mountaineers, thinking it ignominious to marry even with great and rich families of another race. This grade is flattered by the respect paid them by the reft of the martin, and the privileges behavior from them by the government. The hereditary priviles of Spara in this principality are the and semarkably players in this principality are twiced. Gyon, Sparalless, and the Andero.

And The Act of the derivated and the last king of the Modes. He derivated at the last king of the Modes. He derivated the Cambridge with this derivate the last king of Perfia, there shows a vincipality for the last thing of Perfia, there shows a vincipality of the last thing as the figure with child, he resolved to hill the infant as soon

being with child, he relolved to kill the inlant as foon as born. Its name was Cyrus; and Harpagus, being lens to defiroy it, he preserved it : which Aftyages after a long time hearing of, he caused Harpagus to eat his own fon. Harpagus called in Cyrus, who dethroned his grandfather, and thereby ended the monarchy of the Medes. See Media and Persia.

ASTYANAX, the only fon of Hector and Andromache. After the taking of Troy, he was thrown from the top of a tower by Ulysses's orders.

ASTYNOMI, in Grecian antiquity, magistrates in Athens, corresponding with the ædiles of the Romans: they were ten in number. See AEDILE.

ASYLUM, a fanctuary, or place of refuge, where criminals shelter themselves from the hands of justice. The word is compounded of the privative particle a, and ounaw, I bart; because no person could be taken out of an afylum without facrilege.

The afyla of altars and temples were very ancient; and likewife those of tombs, statues, and other monuments of confiderable perfonages. Thus, the temple of Diana Vol. II. Part II.

at Ephelus was a refuge for debtors, the tomb of The- Aylum feus for flaves. Among the Romans, a celebrated aty-lum was opened by Romulus between the mounts Pa-Afyndeton. latine and Capitoline, in order to people Rome, for all forts of persons indiscriminately, fugitive slaves, debtors, and criminals of every kind. The Jews had their afyla; the most remarkable of which were, the fix cities of refuge, the temple, and the altar of burntofferings.

It was customary among the Heathens to allow 1efuge and impunity even to the vilest and most flagrant offenders; fome out of superflition, and others for the fake of peopling their cities: and it was by this means, and with fuch inhabitants, that Thebes, Athens, and Rome, were first stocked. We even read of afylums at Lyons and Vienne among the ancient Gauls; and there are some cities in Germany which still preserve the ancient right of afylum. Hence on the medals of feveral ancient cities, particularly in Syria, we meet with the infeription AEYAOI, to which is added IEPAI. This quality of alylum was given them, according to M. Spanheim, in regard to their temples, and to the gods revered by them.

The emperors Honorius and Theodofius granting the like immunities to churches, the bifliops and monks laid hold of a certain tract or territory, without which they fixed the bounds of the fecular jurifdiction: and fo well did they manage their privileges, that convents in a little time became next akin to fortreffes; where the most notorious villains were in fasety, and braved the power of the magiltrate.

These privileges at length were extended not only to the churches and church-yards, but also to the bishop; houses; whence the criminal could not be removed without a legal affurance of life, and an entire remillion of the crime. The reason of the extension was, that they might not be obliged to live alrogether in the churches, &c. where several of the occasions of life could not be decently performed.

But at length these asyla or sanctuaries were also Aripped of most of their immunities, because they served to make guilt and libertinage more bold and daring. In England, particularly, they were entirely abolified. See SANCTUARY.

ASYMETRY, the want of proportion between the parts of any thing : being the contrary of femme-

ASYMPTOTE, in geometry, a line which continually approaches nearer to another: but though contimued infinitely, will never meet with it: Of these are many kinds. In strictness, however, the term of improtes is appropriated to right lines, which approach nearer and nearer to some curves of which they are faid to be asymptotes; but if they and their curves are indefinitely continued, they will never meet. See Conic

ASYNDETON, in a grammar, a figure which omits the conjunctions in a fentence. As in weni, vidi, vici, where ET is left out: or in that of Cicerq conterning Catiline, abiit, excessit, evasit, erupit : or in that verse of Virgil,

Ferte citi flammas, date vella, impellite remos.

Afyndeton stands opposed to polysyndeton, where the copulatives are multiplied.

Atal-ulu-Aie.

ATABULUS, in physiology, a provincial wind in Apulsa, of a dry pinching quality, and very noxious in its effects. The ancient naturalists speak of the Atabeltis in terms of horror, on account of the ravages it made among the fruits of the earth, which it fcorched or withcred up.

ATABYRIS, a very high mountain in the island of Rhodes, on which, according to Strabo and Diodorus Siculus, there flood a temple of Jupiter Atabyrius, whose worship a colony of Rhodians carried into Sicily, where a temple was built to the same deity

at Agrigentum.

ATALANTA, an island in the Euripus of Euboca, near the Locri Opuntii, faid to have been originally a city of the Local, but torn from the continent in the time of an earthquake, and during an eruption of Mount Ætna. This happened in the fourth year of the 93 Olympiad, in the reign of Artaxerxes Mnemon (Pliny, Orofius).

ATALANTIS, ATLANTICA, OF ATLANTIS. Sec.

ATLANTIS.

ATAKAXY, a term used by the Stoics and Sceptics, to denote that calmness of mind which secures us from all emotions arising from vanity and felf conceit.

ATARGATIS TANUM, the temple of a goddess world topica by the Syrians and Parthians, having the face of a woman and tail of a fish, and called Derceto by the Greeks. Her temple flood in the city Bambyce, called afterwards Harapolis. It was extremely rich, infortuch that Creffus, in his march against the Parthians, fpent feveral days in weighing the treafure. Vollius makes the name of this goddess Phænician, from Addir day, "the great fish."

ATARNEA, an ancient town of Mysia, situated between Adramyttum and Pitane, remarkable for the marriage of Ailftotle with the fifter or concubine of the tyrant Hermas; also for the dotage of that philo-

topher.

ATAXY, in a general fense, the want of order: With physiciaus, it figuries irregularity of crifes and

parosylms of fevers.

ATCIIE, in commerce, a small filver coin used in Turkey, and worth only one-third of the English

ATCHIEVEMENT, in heraldry, denotes the arms of a person or family, together with all the exterior ornaments of the flucld; as helmet, mantle, creft, ferolis, and motto, together with fuch quarterings as may have been acquired by alliances, all marshalled in bider.

ATCHIEVE. This term is derived from the French achever, i. e. to finish or make an end of; but figuifies, in its ordinary acceptation, to perform great

actions or exploits.

ATE, the goddess of mischief, in the Pagan theology. She was daughter of Jupiter, and cast down from heaven at the both of Hercules. For Juno having deceived Jupiter, in causing Eurystheus to be born before Hercules, Jupiter expressed his resentment on Ate, as the author of that mischief: and threw her headlong from heaven to earth, swearing she should never return thither again (Homeri Il. xix. 125.) The name of this goddefs comes from araw, noceo, to "hurt." Her being the daughter of Jupiter, means, according to mythologists, that no evil happens to us but by the

permission of Providence; and her banishment to earth Ategua denotes the terrible effects of divine justice among Athaman-

ATEGUA, or ATTIGUA, an ancient town of Spain, placed by fome in the road from Antiquara, now Antequera, to Hispalis, or Seville; by others near Alcala Real; which last is the more probable situation, because the flumen falfum, now the Salado, was in its neighbourhood. Now Tebala Vieja, or Teixila.

ATELLA, an ancient town of Campania in Italy, between Capua and Neapolis. From this town the Atellang fabule, or Atellam ludi, took their name. Thefe were also called Ofci, from their inventor, in whose territory Atella lay. They were generally a species of farce, interlarded with much ribaldry and bufloonery; and fometimes were exordia or interludes pretented between the acts of other plays. The actors in thefe farces were not reckoned among the common players, nor deemed infamous; but retained the rights of their tribe, and might be listed for foldiers, the privilege only of free men. The ruins of this town are still to be feen about 11 miles from the modern Aversa, which was built out of its materials.

ATEMPO GIUSTO, in music, fignifies to sing or

play in an equal, true, and juk time.

ATERGATIS, in mythology, a goddels of the Syrians, sapposed to be the mother of Semiramis. "She was represented with the face and breaks of a woman, but the rest of her body resembled a fish. fine faye the term figuities swittout ffb, and conjectures that the votaries of this deity abitained from

ATERNUM, a town of Lucania in Italy, now Atorni, (Chaserus): Alia a town in the territory of the Piceni, now Parara, a port town of Maples, fituated on the Adrama, Long, 15. 25 N. Lat.

ATESTE, a some is the tentiney of Version in Italy, now called Big. L. Long. 12. 6 W. Let. 45. 25.

ATHAMADULET and prince equilibre of the Persian empire. It is great space is of the Twester empire. He as great distributes at the languous, greatest of the inamore, and is charged with all foreign and the ATHAMANTA, assures to the menurates called an analysis and the distribute of the distribute of

nynia order, belonging to the pentendria clais of plants; and in the natural method ranking under the 45th order, Umbellate. The fruit is oblong and firiated; and the petals are inflected and emergenment. Of this genus Linnzus enumerates nine fpecies; but none of them merit particular notice, except the cretensis, otherwise called daucus creticus, which grows wild in the Levant and the warmer parts of Europe. The leaves are irregularly disposed, and formed like those of fennel. The flowerftalk rifes about two feet high, fending out many branches, terminated at the top by compound umbels, composed of near 20 small ones. These have white flowers with five petals, which are fucceeded by oblong, hairy, channelled fruit, divided into two parts, containing one oblong hairy feed. The feeds have a warm biting tafte, with an agreeable aromatic smell. They are kept in the shops as a medicine, are carminative, and faid to be diuretic; but are little used in practice. The plant may be propa-

Athanasia, gated from feeds, which should be fown on an open Athana- bed of light dry ground; the following autumn the plants should be taken up, and planted at about a foot distance in a bed of light sandy earth, where the roots will continue feveral years.

> ATHANASIA, GOLDILOCKS: A genus of the polygamia æqualis order, belonging to the fyngenefia class of plants; and in the natural method ranking under the 49th order, Composita discoides. The receptacle is chaffy; the pappus is chaffy, and very short; and the calyx is imbricated. There are 20 species, all tender plants except one; and none of them poffeffed of beauty, or any remarkable property.

ATHANASIAN CREED; a formulary, or confestion of faith, long supposed to have been drawn up by Athanasius bishop of Alexandria, in the fourth century, to justify himself against the calumnies of his Arian enemies. But it is now generally allowed among the learned not to have been his, Dr Waterland ascribes it to Hilary bishop of Arles, for the following among other reasons: 1. Because Honoratus of Marseilles, the writer of his life, tells us, that he composed an Expession of the Creed; a properer title for the Athanafian than that of Greed firmply which it now bears. 2. Hilary was a great admirer and follower of St Austin; and the whole compolition of this creed is in a manner upon St Austin's plan, both with respect to the Trinity and incarnation. 3. It is agreeable to the flyle of History, as far as we as judge from the little shift is left of his works. Up-on the whole, he concludes that Hilary bishop of Arles, shout the year stip, composed The Exposition of Faith, which now better the name of the Athanaof Faith, which now bears the name of the Athanafion Creed, for the nie of the Gallican clergy, and particularly those of the distance of Aries: That, about
the rear cree, it became famous enough to be commention from the that all this while, and for several
years again, but that all this while, and for several
years again, in the many because the name of Athanafian, but was simply highed. The Catholic Faith: That,
before they, Athanasian analysis of the an excellent sythem of the Athanasian principles of the Trinsty and ingrantion, in opposition chiefly to the Atians, Macedomans, and Apollinarians. This is the hypothesis of the bines, and Apollinarians. This is the hypothesis of the learned author of the Critical History of the Athanasian

As to the reception of this creed in the Christian churches, we find, that it obtained in France in the time of Hinemar, or about 850; that it was received in Spain about 100 years later than in France, and in Germany much about the same time. As to our own country, we have clear and positive proofs of this creed being fung alternately in our churches in the tenth century. It was in common use in some parts of Italy, particularly in the diocese of Verona, about the year 960, and was received at Rome about the year 1014. As to the Greek and oriental churches, it has been questioned whether any of them ever received this creed at all; though some very confiderable writers are of a contrary perfuasion. It appears then, that the reception of this creed has been both general and ancient; and may vie with any, in that respect, except the Nicene, or Constantinopolitan, the only general creed common to all the churches.

'As to the matter of this creed, it is given as a fum-

mary of the true orthodox faith, and a condemnation Athanahus of all herefies ancient and modern. Unhappily, however, Athanor. it has proved a fruitful fource of unprofitable contro-, verfy and unchristian animosity even down to the prefent time.

ATHANASIUS (St), bishop of Alexandria, and one of the greatest defenders of the faith against the Arians, was born in Egypt. He followed St Alexander to the council of Nice, in 325, where he disputed against Arius, and the following year was made bishop of Alexandria; but, in 335, was deposed by the council of Tyre: when, having recourse to the emperor Constantine, the Arian deputies accused him of having hindered the exportation of corn from Alexandria to Constantinople: on which the emperor, without fuffering him to make his defence, banished him to Treves. The emperor, two years after, gave orders that he should be restored to his bishopric; but, on his return to Alexandria, his enemies brought fresh accufations against him, and hose Gregory of Cappadocia to his fee; which obliged Athanafius to go to Rome to reclaim it of Pope Julius. He was there declared innocent, in a council held in 342, and in that of Sardica in 347, and two years after was restored to his fee by order of the emperor Constans; but after the death of that prince, he was again banished by the emperor Conftantine, which obliged him to retire it to the deferts. The Arians then elected one George in his room; who being killed in a popular fedition under Julian in 360, St Athanasius returned to Alexandria, but was again banished under Julian, and restored to his fee under Jovian. He addressed to that emperor a letter, in which he proposed that the Nicene creed should be the standard of the orthodox faith, and condemned those who denied the divinity of the Holy Ghoft. He was also banished by Valens in 367, and afterwards recalled. St Athanafius died on the 2d of May 373.

His works principally contain a defence of the myflery of the Trinity, and of the incarnation and divi nity of the Word and Holy Spirit. There are three editions of his works which are effected; that of Commelin, printed in 1600; that of Peter Namius, in 1627; and that of Father Montfaucon. As to the creed which bears his name, fee the preceding article.

ATHANATI, in Perfian antiquity, a body of cavalry, confifting of 10,000 men, always complete. They were called athanati (a word originally Greek, and fignifying immortal), because, when one of them happened to die, another was immediately appointed to fucceed him.

ATHANOR. Chemifts have diffinguished by this name a furnace to constructed that it can always maintain an equal heat, and which shall last a long time without addition of fresh suel.

The body of the athanor has nothing in it particular, and is confiructed like ordinary furnaces.' But at one of its fides, or its middle, there is an upright hollow tower, which communicates with the fireplace by one or more floping openings. This tower ought to have a lid which exactly closes its upper opening.

When the athanor is to be used, as much lighted coal is put in the fire place as is judged necessary, and the tower is filled to the top with unlighted fuel. The

Athanor tower is then to be exactly closed with its lid. As fast as the coal in the fire-place is confumed, that in the tower falls down and supplies its place. As the coal contained in the tower has no free communication with the external air, it cannot burn till it falls into the fire-place.

The athanor being much celebrated and used by ancient chemists, it has been particularly described by many authors, and was formerly found in all laborato-1108. At present this furnace is much less employed, and is even neglected. The reason of this is, that all the ancient chemists were in search of the art of making gold; and being excited by this powerful defire, and confidence of fuccess, they spared no trouble nor expence to accomplish this design. They undertook, without hefitation, operations which required great length of time and unremitted heat. Whereas now, thefe alluring hopes having vanished, the cultivators of chemistry have no other view than to extend and sper-1. If the theory of this effential part of natural philosophy. This motive, although undoubtedly much nobler than the former, feems, however, to be left powerful over most men. For now, all long and laborious operations whence chemistry might receive great advantayes, are neglected, as being tirefome and difgullful. There is, in fact, a confiderable difference betwizt the hope of explaining a philosophical phenomenon, and that of obtaming an ingot of gold capable of producing many others. Hence the instruments employed in long operations, and particularly the athanor, are now much reglected; and also because the fuel in the tower is apt to flick there or fall down at once in too great quantity. The lamp-furnace, which is a true athanor, may be fuccefsfully employed in operations which do not require much heat.

ATHAROTH, or Atroth, (anc. geog.), the name of feveral towns. Two appear to have been in Sunaria, in the tribe of Ephraim; the one four miles to the north of Sebafte, or the city of Samaria; the other in the confines of Benjamin and Ephraim, yet of as to be in the diftrict of Ephraim rather than of Benjamin (Joshua). This is the Ataroth Addar mentioned Johna xvi. 5. from which to Upper Beth-horon extends the greatest breadth of the tribe of Ephraim.

ATHEISM, the difbelief of a deity. See A-

ATHEIST, a person who does not believe the existence of a Deity. Many people, both ancient and modern, have pretended to atheifm, or have been reckoned atheifts by the world; but it is juftly questioned whether any man feriously adopted such a principle. These pretentions, therefore, must be founded on mide or affectation.

Atheism, as absurd and unreasonble as it is, has had its martyrs. Lucilio Vanini, an Italian, native of Naples, publicly taught atheism in France, about the beginning of the 17th century; and, being convicted of it at Toulouse, was condemned to death. Being preffed to make public acknowledgment of his crime, and to ask pardon of God, the king, and justice, he answered, he did not believe there was a God: that he never offended the king; and, as for justice, he wished it to the devil. He confessed that he was one of twelve, who parted in company from Naples to pread their doctrine in all parts of Europe.

tongue was full cut out, and then his body burnt, A. Atheling

Cicero represents it as a probable opinion, that they Athenaus who apply themselves to the study of philosophy believe there are no gods. This must, doubtlefs, be meant of the academic philosophy, to which Cicero himself was attached, and which doubted of every thing. On the contrary, the Newtonian philosophers are continually recurring to a Deity, whom they always find at the end of their chain of natural causes. Some foreigners have even charged them with making too much use of the notion of a God in philosophy, contrary to the rule of Horace:

Nec Deus interfit, nifi dignus vindici nodus. Among us, the philosophers have been the principal advocates for the existence of a Deity. Witness the writings of Sir Isaac Newton, Boyle, Ray, Cheyne, Nieuwentyt, &c. To which may be added many others, though of the clergy (as was also Ray), yet have diffinguished themselves by their philosophical pieces in behalf of the existence of a God; e. gr. Derham, Bentley, Whiston, Samuel and John Clarke, Fencion, &c. So true is that faying of Lord Bacon, that though a farettering of philosophy may lead a man into atheim, a deep draught will certainly bring him back again to the belief of a God and Pro-

ATHELING, Adresed, Edling, Ethling, or ETUTING, ADDRESS, FIRENCE, ETHING, OF ETUTING, among the Anglo-Samons, was a title of honour properly belonging to the heir apparent, we predumptive to the majority. This honours has apparent tion was first conferred by Ling Edward the Conferred on Edgar, to whom he was given uncle, when being without my flue of his associate intended to make him his heir. his heir

A FEEL AND A CHARLES OF Implies a strength of the first o

called Athens.

ATHENAUM, in antiquity, a public place wherein the professors of the liberal arta held their assemblies, the thetoricians declaimed, and the poets rehearf, ed their performances. These places, of which there. were a great number at Athens, were built in the man, ner of amphitheatres encompassed with seats, called cunei. The three most celebrated Athenca were those at Athens, at Rome, and at Lyons, the second of which was built by the emperor Adrian.

ATHENÆUS, a physician, born in Cilicia, cotemporary with Pliny, and founder of the pneumatisfect. He taught that fire, air, water, and earth, are not the true elements, but that their qualities are, viz. heat, cold, moisture, and digness; and to these he added a fifth element, which he called (pirita whence his feet had its name.

ATHENÆUS, a Greek grammarian, born at Nau-

Athens.

By whom

Lounded.

Athenago- cratis in Egypt in the 3d century, one of the most learned men of his time. Of all his works we have none extant but his Deipnosophis, i. e. the sophists at table; there is an infinity of facts and quotations in this work which render it very agreeable to admirers of antiquity.

> There was also a mathematician of this name, who wrote a treatife on mechanics, which is inferted in the works of the arcient mathematicians, printed at Paris

in 1603, in folio, in Greek and Latin.

ATHENAGORAS, an Athenian philosopher, flourished about the middle of the 2d century; and was remarkable for his zeal for Christianity, and his great learning, as appears from the apology which he addreffed to the emperors Marcus Aurelius Antoninus and Lucius Commodus.

ATHENODORUS, a famous Stoic philosopher, born at Tarfus, went to the court of Augustus, and was made by him tutor to Tiberius. Augustus had a great efteem for him, and found him by experience a man of virtue and probity. He used to speak very freely to the emperor. He, before he left the court to return home, warned the emperor not to give himfelf up to anger, but whenever he should be in a passion, to rehearle the 24 letters of the alphabet before he resolved to say or do any thing. He did not live to see his bad success in the education of Tiberius.

ATHENOPOLIS, a town of the Massilienses, an ancient nation of Gaid. It is conjectured by Hardovin to be the same with Tele Murtins, now Toulon; by others to be the fame with dampoles or duibes.

ATHENREE, a town of freland, in the county of ATHERICS, a town of freiand, in the county of Catway, and province of Counsessts. W. Long. 8. 5. N. Lat. 52: 74. It is a merced by a portrieve, and hath a house keep three communics of foot. It hath being a section of a merced by a portrieve, and hath a house for confidential freezests; but, like the confidence to the last tables which three out, his confidence of the fill beautifully as menuments of hather or grandour.

ATHENS, a celebrated of Course, and capital of the ancient himself of Course, independent of Course, and capital of the ancient himself of Course, independent of Course, and capital of the ancient himself of Course.

of his she ancient hand dutte of Artica, fituated in Liong 53. N. Let. 36. 2 See Artica.
In sarly times, that which was afterwards called the

chiefel was the whole city; and went under the name of Cerropia, from its founder Cecrops, whom the Athenians in after times affirmed to have been the first builder of cities, and called this therefore by way of eminence Polis, i. e. the city. In the reign of E. richthonius it lost the name of Cecropia, and acquired that of Athens, on what account is not certain; the most probable is, that it was so named in respect to the goddess Minerva, whom the Greeks call Athene, who was also esteemed its protectress. This old city was feated on the top of a rock in the midit of a large and pleasant plain, which, as the number of inhabitants increased, became full of buildings, which induced the distinction of Acro and Catapolis, i. e. of the upper and lower city. The extent of the citadel was 60 stadia; it was furrounded by olive trees, and fortified, as fome fay, with a strong palifade; in succeeding times it was encompassed with a strong wall, in which there were nine gates, one very large one, and the reft small. The inside of the citadel was adorned with in-

numerable edifices. The most remarkable of which Athens. were, 1. The magnificent temple of Minerva, ftyled parthenion, because that goddess was a virgin. The 2
Persians destroyed it; but it was rebuilt with shill shie buildgreater splendour by the samous Pericles, all of theings. finest marble, with such skill and strength, that, in spite of the rage of time and barbarous nations, it remains perhaps the first antiquity in the world, and stands a witness to the truth of what ancient writers have recorded of the prodigious magnificence of Athens in her flourishing state. 2. The temple of Neptune and of Minerva; for it was divided into two parts; one facred to the god, in which was the falt fountain faid to have fprung upon the stroke of his trident; the other to the goddels protectress of Athens, wherein was the facred olive which the produced, and her image which fell down from heaven in the reign of Erichthonius. At the back of Minerva's temple was the public treasury, which was burnt to the ground through the knavery of the treasurers, who, having misapplied the revenues of the state, took this short method of making up ac-

The lower city comprehended all the buildings furrounding the citadel, the fort Munychia, and the havens Phalerum and Pirans, the latter of which was ioined to the city by walls five miles in length; that on the north was built by Pericles, but that on the fouth by Themistocles; but by degrees the turnets which were at first creeted on those walls were turned into dwelling houses for the accommodation of the Athenians, whose large city was now become too small for them. The city, or rather the lower city, had 13 great gates, with the names of which it is not needly fary to trouble the reader. Among the principal edifices which adorned it, we may reckon, 1. The temple of Thefeus, creeted by Conon, near its centre. Adjacent thereto, the young people performed their exercifes. It was also a fanctuary for diffressed persons, flaves or free. 2. The Olympian temple erected in honour of Jupiter, the glory of Athens, and of all Greece. The foundation of it was laid by Pilistratus: it was carried on but flowly in fucceeding times, 700 years elapfing before it was finished, which happened under the reign of Adrian, who was particularly kind to Athens: this was the first building in which the Athenians beheld pillars. 3. The pantheon, dedicated to all the gods; a most noble structure, supported by 120 marble pillars, and having over its great gate two borfes carved by Praxiteles: it is yet remaining, as we shall have occasion to show hereafter when we come to speak of the present state of this famous city. In several parts of it were faoi or porticoes, wherein people walked in rainy weather, and from whence a feet of philosophers were denominated Stoics, occause their master Zeno taught in these porticoes.

There were at Athens two places called Ceramicus, Commicus from Ceramus the fon of Bacchus and Ariadne; one within the city, containing a multirude of buildings of all forts; the other in the fuburbs, in which was the academy and other edifices. The gymnafia of Athens were many; but the most remarkable were the Lyceum. Academia, and Cynolarges. The Lyceum flood on the banks of Iliffus; some fay it was built by Pisistratus, others by Perichs, others by Lycurgus. Here Ariftotle taught philosophy, instructing such as came

Athens, to hear him as they walked, whence his disciples are generally thought to derive the name of Peripatetics. The Ceramicus without the city was the distance of fix stadia from its walls. The academy made part thereof; as to the name of which there is some dispute. Some affirm that it was so called from Academus, an ancient hero, who, when Helen was stolen by Theseus, discovered the place where the lay hid to Castor and Pollux: for which reason the Lacedemonians, when they invaded Attica, always spared this place. Dicarchus writes, that Caftor and Pollux had two Arcadians in their army, the one named Erbedemus, the other Marothus; from the former of these he says this place took its name, and that the borough of Marathon was fo called from the other. It was a marshy nawholesome place, till Cimon was at great pains to have it drained; and then it became extremely pleasant and delightful. being adorned with shady walks, where Plato read his lectures, and from thence his scholars were flyled Acedemics. The Cynofarges was a place in the intuities Cynolarges not far from the Lyccum: it was famous on many counts; but particularly for a noble gymnatium erected there, appointed for the special use of fach as were Athenians only by one fide. In after times Themis stocles derived to himself ill will, by carrying many of the nobility to exercise with him here, because, being but of the half blood, he could exercise nowhere else but in this gymnafium. Antifthenes inflituted a feet of philosophers, who from the name of this diffrict, as many think, were flyled Cynics.

Haven.

The havens of Athens were three. First, the Piretts, which was diffant about 35 or 40 fladia from the city, till joined thereto by the long walls before-mentioned. after which it became the principal harbour of the city. It had three docks; Cantharos, Aphrodisum, and Zear the first was so called from an ancient hero, the fecond from the goddess Venus who had there two temples. and the third from bread corn. There were in this port five porticoes, which joining together formed time great one called from thence Macra Ston, or the grand portico. There were likewise two great markets or fora; one near the long portico, the other near the city. The second port was Munychia, a promontory not far distant from Piræus; a place very strong by nature, and afterwards rendered far ftronger by, art. It was of this that Epimenides said, if the Athenians forefaw what mischief it would one day produce to them, they would eat it away with their teeth. The third was Phalerum, distant from the city, according to Thucydides 35 stadia, but according to Pausanias only 20. This was the most ancient harbour of A. thens, as Piræus was the most capacious.

Prefent ftate.

Of this city, as it stands at present, we have the following account by Dr Chandler. " It is now called Athini; and is not inconfiderable, either in extent or the number of inhabitants. It enjoys a fine temperature, and a serene sky. The air is clear and wholesome, though not so delicately soft as in Ionia. The town flands beneath the acropolis or citadel; not encompassing the rock as formerly, but spreading into the plain, chiefly on the west and north-west. Corfairs infesting it, the avenues were secured, and in 1676 the gates were regularly shut after sunfet. It is now open again; but several of the gateways remain, and a guard of Turks patrols at midnight. Some masses of

brick work, standing separate, without the town, be. Athens. longed perhaps to the ancient wall, of which other traces also appear. The houses are mostly mean and straggling; many with large areas or courts before them. In the lanes, the high walls on each fide, which are commonly white-washed, restect strongly the heat of the fun. The streets are very irregular; and anciently were neither uniform nor handsome. They have water conveyed in channels from Mount Hymettus, and in the bazar or market place is a large fountain. The Turks have feveral mosques and public baths. The Greeks have convents for men and women; with many churches, in which fervice is regularly performed; and befides thefe, they have numerous oratorics or chapels, fome in ruins or confifting of bare walls, frequented only on the anniversaries of the faints to whom they are dedicated. A portrait of the owner on a board is placed in them on that occasion, and removed when the following of the day is over.

"The city of Cecrops is now a fortress with a thick Citadel, or irregular wall, Asading on the brink of precipices, and city of Ceenclosing a large area about twice as long as broad, crops.

Some portions of the ancient wall may be discovered dome portions of the ancient wall may be discovered on the outlide, particularly at the two extreme angles; and is many places it is patched with pleces of columns and with marbles taken from the rums. A confidentiale from had been recently expended on the fide start Flymettus, which shas inside defore we arrived. The fashfolding had been removed to the cod toward Powels, but mosey was wanting, and the workman were witadowing. The garantial consults of a few Turks, who relate these title their senting. Bird are called by the Cardels Cofficient of the fashion of the patched by the Cardels Cofficient of the fashion of the patched by the Cardels Cofficient of the fashion of the treat, what is some and the first in flat on that construct a first manual and the first in the construction of the front what is a sent to the first warm of the construction of the sent point on the outlide, particularly at the two extreme angles;

as to fumply Polemo Periogetes with marter for four volumes; and Strabo affirms, that as many would be required in treating of other portions of Athens and of Atties. In particular, the number of flatues was prodigious. Tiberius Nero, who was fond of insages; plundered the acropolis as well as Delphi and Olyma pia; yet Athens, and each of thefe places, had not fewer then 3000 remaining in the time of Pliny. Even Paufanius feems here to be distressed by the multiplicity of his subject. But this banquet, as it were, of the fenfes has long been withdrawn; and is now become like the tale of a vision. The spectator views with concern the marble ruins intermixed with meanflat-roofed cottages, and extant amid rubbish: the sad memorials of a nobler people; which, however, as vifible from the sea, should have introduced modern A- Athens, thens to more early notice. They who reported it was only a fmall village, must, it has been furmifed, have beheld the acropolis through the wrong end of their telescopes.

> "The acropolis has now, as formerly, only one entrance, which fronts the Piræus. The afcent is by traverses and rude fortifications furnished with cannon, but without carriages and neglected. By the second gate is the flation of the guard, who fits crofs-legged under cover, much at his ease, smoking his pipe, or drinking coffee, with his companions about him in like attitudes. Over this gate-way is an infeription in large characters on a stone turned upside down, and black from the fires made below. It records a prefent of a pair of gates.

Propyléa.

Temple W

" Going farther up, you come to the ruins of the propyléa, an edifice which graced the entrance into the citadel. This was one of the Aructures of Pericles, who began it when Euthymenes was archon, 435 years before Christ. It was completed in five years, at the expence of 2012 talents. It was of marble, of the Doric order, and had five doors to afford an easy paffage to the multitudes which reforted on business or devotion to the acropolis.

" While this fabric was building, the architect Mineficles, whose activity equalled his skill, was hare by a fall, and the physicians despaired of his life; but Minerva, who was propitions to the undertaking, appeared, it was faid, to Pericles, and preferibed a remedy, by schick he was speedily and cally cured. It was a

the spinels he was facedly and cally cured. It was a plant or being growing sound about the acropolis, and called later water proposition.

The type imag of the propyles was a temple of Vectors. They stated that fageus had shoot there, cawing the less shift amount for the rotates of his fon-Phichaga must the account for the rotates. The selfet which was the delivered for the selfet which was the delivered for the factor of the selfet which was the delivered for the selfet which was the selfet of the s be conqueror. It had a pomegranate in the right hard and a holmet in the left. As the dates was without pissous, it was hoped the goddels would remain for ever on the fpot.

"On the left wing of the propyles, and fronting the semple of Victory, was a building decorated with paintings by Polygnotus, of which an account is given by Paulanius. This edifice, as well as the temple, was of the Doric order, the columns fluted, and without bales. Both contributed alike to the uniformity and grandeur of the defign; and the whole fabric, when finished, was deemed equally magnificent and ornamental. The interval between Pericles and Paulanius confilts of feveral centuries. The propyléa remained entire in the time of this topographer; and, as will be fhown, continued nearly fo to a much later period. It had then a roof of white marble, which was unfurpassed either in the fize of the stones or in the beauty of their arrangement; and before each wing was an equeftrian statue.

"The propylea have cealed to be the entrance of Athens. the acropolis. The passage, which was between the columns in the centre, is walled up almost to their capitals, and above is a battery of cannon. The way now winds before the front of the ancient ftructure; and turning to the left hand among rubbish and mean walls, you come to the back part, and to the five door-ways. The foil without is rifen higher than the

top of the two smaller. There, under the vault and cannon, lies a heap of large stones, the ruin of the

roof.

"The temple of Victory, standing on an abrupt rock, has its back and one side encumbered with the modern ramparts. The columns in the front being walled up, you enter it by a breach in the fide, within the propydea. It was used by the Turks as a maga-Roof carzine for powder, until about the year 1656, when a ried off by fudden explosion, occasioned by lightning, carried away fion. the roof, with a house erected on it, belonging to the officer who commanded in the acropolis, whose family, except à girl, perished. The women of the aga contiqued to inhabit in this quarter, but it is now abandoned and in runs.

The cell of the temple of Victory, which is of white marble, very thick, and strongly cemented, fufficiently witnesses the great violence it has undergone; the stones in many places being disjointed, as it were, mid forced from their original polition. Two of these making an acute angle, the exterior edges touching, without a crevice; and the light abroad being much stronger than in the room, which has a modern roof and is dark; the portion in contact becoming pellucid, had illumined the vacant space with a dim colour resembling that of amber. We were defined to examine this extraordinary appearance, which the Greeks regarded as a standing miracle, and which the Turk., who could not confute them, beheld with equal aftomilliment. We found in the gap some coals, which had been brought on a bit of earthen ware for the purpole of hurning incense, as we supposed, and also a piece of wax-taper, which probably had been lighted in honour of the faint and author of the wonder; but our Swife unfortunately carrying his own candle too far in, the fmoke blackened the marble, and defroyed the phenomenon.

The building opposite to the temple has served as a foundation for a fquare lofty tower of ordinary mafonry. The columns of the front are walled up, and the entrance is by a low iron gate in the fide. It is now used as a place of confinement for delinquents; but in 1676 was a powder magazine. In the wall of a rampart near it are some fragments of exquilite sculpture, representing the Athenians fighting with the Amazone. These belong to the freeze, which was then standing. In the second century, when Pausanias lived, much of the painting was impaired by age, but some remained, and the subjects were chiefly taken from the Trojan

The traces are fince vanished.

"The pediment of the temple of Victory, with that of the opposite wing, is described as remaining in 1676; but on each building a square tower had been errected. One of the steps in the front of the propyléa was entire, with the four columns, their entablature and the pediment. The portico, to which the five doorways belonged, confilted of a large square room, roof-

Athens. ed with flabs of marble, which were laid on two great marble beams and fustained by four beautiful columns. These were Ionic, the proportions of this order best futting that purpose, as taller than the Doric; the reason it was likewise preferred in the pronaos of the temple of Victory. The roof of the propyléa, after standing above 2000 years, was probably destroyed, with all the pediments, by the Venetians in 1687, when they battered the castle in front, firing red hot bullets and took it, but were compelled to refign it again to the Turks in the following year. The exterior walls, and in particular, a fide of the temple of Victory, retain many marks of their hotbilities.

Temple of Minerva.

"The chief ornament of the acropolia was the parthenon or great temple of Minerva, a most superb and magnificent fabric. The Persians had burned the edifice, which before occupied the fite, and was called becatompedan, from its being 100 feet fquare. The zeal of Pericles and of all the Athenians was exerted in providing a far more ample and glorious religence for their favourite goddels. The architects were Callicrates and Ictinus; and a treatife on the building was written by the latter and Carpion ... It was of white marble of the Doric order, the columns fluted and without bases, the number in front eight; and adorned with admirable sculpture. The story of the birth of Minerva was carved in the front pediment and in the back, her contest with Neptune for the country. The beatts of burden, which had converted up the materials, were regarded as facred, and recompenfed with pastures; and one which had voluntarily: headed the train, was maintained during life, withoutlabour, at the public expence.

Har ftatue.

The statue of Minerva, made for this temple by: Phidias, was of ivory, 26 cubits or 39 feet high. was decked with pure gold to the amount of 44 to lents, fo disposed by the advice of Pericles as to be taken off and weighed, if required. The goddeft, wie represented flanding, with her vestment reaching her feet. Her helmet had a fphinx for the croft. on the fides were griffins. The head of Medny was on her breaftplate. In one hand ihe beld her town and in the other supported an image of Victory four cubits high. The battle of the Cestains, and Lapithæ was carved on her fandals; and on the many which lay at her feet, the war of the gods and grants and the battle of the Athenians and Amezon. her fpear was a ferpent, in allufion to the flory of richthonius; and on the pedeftal, the birth of Pands ra. The Sphinx, the Victory, and Serpent, were counted eminently wonderful. This image was placed in the temple in the first year of the 87th Olympiad, in which the Peloponnesian war began. The gold was stripped off by the tyrant Lachares, when Demetring Poliorcetes compelled him to fly. The fame plunderer plucked down the golden thields in the acropolis, and carried away the golden Victories, with the precious vessels and ornaments provided for the Panathenzau Matival.

The parthenon remained entire for many ages after it was deprived of the goddefs. The Christians converted it into a church, and the Mahometans into a mosque. It is mentioned in the letters of Crusius, and miscalled the partheon, and the temple of the unknown God. The Venetians under Koningsmark,

when they belieged the acropolis in 1687, threw a Athens bomb, which demolished the roof, and, setting fire to fome powder, did much damage to the fabric. The floor which is indented, still witnesses the place of its. fall. This was the fad forerunner of farther destruction; the Turks breaking the stones, and applying them to the building of a new mosque, which stands within the ruin, or to the repairing of their houses and the walls of the fortress. The vast pile of ponderous materials, which lay ready, is greatly diminished; and the whole structure will gradually be consumed and

disappear. 13
"The temple of Minerva in 1676 was, as Wheeler Temple and Spon affert, the finest mosque in the world, with-converted

out comparison. The Greeks had adapted the fabric mosque. to their geremonial by constructing at one end a femicircular recess for the holy tables, with a window: for before it was enlightened only by the door, obscurity being preferred under the keathen ritual, except on festivals, when it yielded to splendid illuminations; the realon, it has been furmiled, why temples are commostly found limple and unadorned on the infides. In the wall beneath the mindow were interted two pieces of the flone called phengues, a perior of marble difor the mone caused measure, a species of markie discounted in Cappodocia is the time of Percer and so dissipation when the conclusion within a semple to Formation which extends was leading to state when the doctories history. These pieces were predicted, and the light which extends was imaged with a resident or yellowith time. The picture of the Paugets or Kurpin Markins wellass, on the adding of the meeting to province which is the province of the province low, and of an above. The Add one was pear to tracer which by that disposition was less wide as embatralled. In the portice were lafarided lamps, to be used in the malque at the featons at the Muselmans affemble before day-breaks at to lighted up round the minaret, as is the entire their Ramazan or Lent.

"It is not easy to conceive a more fraking object Magnific than the parthenon, though now a mere ruin. The co-cent ruin. lumns within the naos have all been removed : but on the floor may be feen the circles which directed the workmen in placing them; and at the farther end is a groove across it, as for one of the partitions of the cell. The recess erected by the Christians is demolished; and from the rubbish of the ceiling the Turkish,

Athens. boys collect bits of the mosaic, of different colours, which composed the picture. We are told at Smyrna, that this substance had taken a polish, and been fet in buckles. This cell is about half demolished; and in the columns which furrounded it is a large gap near the middle. On the walls are some traces of the paintings. Before the portico is a refervoir funk in the rock, to supply the Turks with water for the purifications customary on entering their mosques. In it, on the left hand, is the rubbish of the pile erected to supply the place of a column; and on the right, a staircale, which leads out on the architrave, and has a marble or two with infcriptions, but worn fo as not to be legible. It belonged to the minaret, which has been

destroyed. Sculptures.

"The travellers, to whom we are indebted for an account of the mosque, having likewise given a description of the sculpture then remaining in the front. the middle of the pediment was feen a bearded Jopiter, with a majestic countenance, standing, and naked; the right arm broken. The thunderbolt, it has been suppoled, was placed in that hand, and the eagle between his feet. On his right was a figure, it is conjectured, of Victory, clothed to the mid leg; the head and arms gone. This was trading on the hories of a car, in which Mineten list, young and minemed; her head dreft, infless of a horner, resembling that of a Vertica. The made of a horner, resembling that of a Vertica. The made of a horner and lively fairly middle in this man of orbital farens, was furth as helpooke the handout. Another takes and believet, of a Phidian or Parished Making Mineral and figure, without a series of a property without the same of the series of a property without the same of the series of a property of an inches. gone. This was leading on the bottles of a cert in places among constants of the places o in limites finely executed, with fone muchared figures; and on the architrave beneath them are marks of the Training of rotive offerings, perhaps of the golden when the semple was drelled out to receive the votaries of the guiddels.

"Mentune and Minerva, once rival deities, were tolar and amicable tenants of the Erectheum, in which was an alter of Oblivion. The building was double, spartition wall dividing it into two temples, which fronted different ways. One was the temple of Neptime Erectheus, the other of Minerva Polias. The latter was entered by a square portico connected with a marble skreen, which fronts towards the propyléa. The door of the cell was on the left hand: and at the

Erechéum.

farther end of the passage was a door leading down in- Athens. to the Pandroleum, which was contiguous.

"Before the temple of Neptune Erectheus was an Temple of altar of Jupiter the fupreme, on which no living thing Neptune was facrificed, but they offered cakes without wine. Erecthous, Within it was the altar of Neptune and Erectheus; and two, belonging to Vulcan and a hero named Buter, who had transmitted the priesthood to his posterity, which were called Butade. On the walls were paintings of this illustrious family, from which the priestels of Minerva Polias was also taken. It was afferted that Neptune had ordained the well of falt water, and the figure of a trident in the rock, to be memorials of his contending for the country. The former, Paulanias, remarks, was no great wonder, for other wells of a fimilar nature were found inland; but this, when the fouth wind blew, afforded the found of

" " The temple of Minerva Polias was dedicated by Of Miners all Attica, and possessed the most ancient statue of Polius. the goddes. The demi or towns had other deities, but their zeal for her fuffered no diminution. The image, which they placed in the acropolis, then the city, was in after ages not only reputed confummately holy, but believed to have fallen down from heaven in the reign of Erichthonius. It was guarded by a large ferpent, which was regularly ferved with offerings of honeyed cakes for his food. This divine reptile was of great fagacity, and attained to an extraordinary age. He wifely withdrew from the temple, when in danger from the Medes; and, it is faid, was living in the fegolden lamp. Before this statue was an owl; and a golden lamp. This continued burning day and night. It was contrived by a curious artist, named Callimachus, and did not require to be replenished with oil oftener than once a year. A brazen palm tree, reaching to the roof, received its smoke. Anstion had let the boly flame expire while Sylla befieged him, and was abhorred for his impiety. The original olive tree, faid to have been produced by Minerva, was kept in this temple. When the Medes fet fire to the acropolis, it was confumed; but, they afferted, on the following day, was found to have shot up again as much as exhit, It grew low and crooked, but was effected wery holy. The priestess of Minerva was not allowed to eat of the new cheefe of Attica; and, among her perquifites, was a measure of wheat, and one of barley, for every birth and burial. This temple was again burned when Callias was archon, 24 years after the death of Pericles. Near it was the tomb of Cecrops, and within it Erecheus was buried.

The ruin of the Erectheum is of white marble: the architectural ornaments of very exquisite workmanflip, and uncommonly curious. The columns of the front of the temple of Neptune are standing with the architrave; and also the skreen and portico of Minerva Polias, and with a portion of the cell retaining traces of the partition wall. The order is Ionic An edifice revered by ancient Attica, as holy in the highest degree, was in 1576 the dwelling of a Turkish family, and is now deferted and neglected; but many ponderous stones and much rubbish must be removed before the well and trident would appear. The former, at least, might probably be discovered. The portice is used as a powder magazine; but we obtained permis-

Athens fion to dig and examine the outfide. The door-way of the vestibule is walled up, and the foil rifen nearly to the top of the door-way of the pandrofcum. By the portico is a battery commanding the town, from which afcends an amufing hum. The Turks fire from at, to give notice of the commencement of Ramazan or of their Lent, and of bairam or the holidays, and on other public occasions.

"The pandroféum is a fmall, but very particular building, of which no fatisfactory idea can be communicated by description. The entablature is supported by women called Caryatides. Their flory is thus related: The Greeks, victorious in the Persian war, jointly destroyed Carya, a city of the Peloponnesus, which had favoured the common enemy. off the males, and carried into captivity the women, whom they compelled to retain their former drefs and ornaments, though in a flate of fervitude. The architects of those times, to perpetuate the memory of. their punishment, represented them, as in this inflance, each with a burden on her head, one hand uplifted to it, and the other hanging down by her fide. The images were in number fix, all looking toward the pasthenon. The four in front, with that next to the propyléa, remain, but mutilated, and their farce and imeared with paint. The foil is rifen almost to the top of the basement on which they are placed. This temple was open or latticed between the flatues; and in it also was a stunted olive tree, with an altar of Ju-piter Herceus standing under it. The propyléa are nearly in a line with the space dividing it from the parthenon; which disposition, besides its other effects, norafioned the front and flank of the latter edifice to be feen at once by those who approached it from the entrance of the acropolis.

Of Jupiter Olympius.

" The ruin of the temple of Jupiter Olympius confifts of prodigious columns, tall and beautiful, of the Counthian order, fluted; fome fingle, fome fupporting the architraves; with a few massive marbles beneath, the remnant of a vast heap, which only many ages could have confumed and reduced into so scanty a compair. The columns are of very extraordinary dimensions, being about fix feet in diameter, and near 60 in height. The number without the cell was 116 or 120. Seventeen were flanding in 1676: but a few years before we arrived, one was overturned with much difficulty, and applied to the building a new molque in the bazzer or market-place. This violence was avenged by the bashaw of Negropout, who made it a pretest for extorting from the vaiwode or governor 15 purles; the pillar being, he alleged, the property of their mafter the grand fignior. It was an angular column, and of consequence in determining the dimensions of the We regretted that the fall of this mighty mass had not been postponed until we came, as it would have afforded an opportunity of inspecting and meafuring some members which we found far too lofty to be attempted. On a piece of the architrave, supported by a couple of columns, are two parallel walls, of modern moloury, arched about the middle, and again near the top. You are told it has been the habitation of a hermit, doubtless of a Stylites; but of whatever building it has been part, and for whatever purpose defigned, it must have been erected thus high in air, while the immense ruin of this huge tructure was yet

fearcely diminished, and the heap inclined so as to ren- Athens, der it accessible. It was remarked that two stones of Atherina. a step in the front had coalesced at the extremity, fo that no juncture could be perceived; and the like was discovered also in a step of the parthenon. In both inflances it may be attributed to a concretory fluid, which pervades the marble in the quarry. Some portion remaining in the pieces, when taken given as it were, and placed in mutual contact, it exuded and united them by a process similar to that in a bone of an animal when broken and properly fet.

" Belides the more stable autiquities, many detach-Detached ed pieces are found in the town, by the fountains, in pieces of anthe streets, the walls, the houses, and churches. A tique sculpmong these are fragments of sculpture; a marble chair ture, &c. or two, which probably belonged to the gymnalia or theatres: a fun-dial at the catholicon or cathedral, inscribed with the name of the maker; and, at the archiepifcopal house close by, a very curious vessel of marble, used as a cittern to receive water, but once ferving, it is likely, as a public flundard or measure. Masy columns occur; with fome maimed flatues; and medestals, several with inscriptions, and shoot buried in carth. A custom has prevailed, as at Chios, of In farth. A culton has prevailed, as at Chios, of fitting in the wall, over the gateways and moors of the matter, carred flories, most of which exhibit the fune set dropped. In this courts of the houses he many round deits, are pillets, pace placed on the graves of the fallowing a point a great number are full to be free applied to the lane are in the Freehold burying grounds before the acceptable. The lane generally have monetic interpretane containing the name of the previous, and of the town and tribe to which his defined a helonged. Demetrian the Phalesian was endominated to refusion fepulchial the record triated Hen ches, see of Palabrates, coulded borough inners, and by the ros moral apophithegase so cleguer verses the vehicles of influction."

ATHERINA, in ichthyology, a present al of the order of abdominules. The characters of genus are their: The upper jaw is place a the says of the branchiostege membrane are fix; and the fire belt or line shines like filver. The species are two wit. 1. The hepfetus, with about 12 mays in the fun pent the anus. It is found in the Mediterranean. It is also very common in the fea near Southampton, where it is called a fuelt. The highest scason is from March to the latter end of May, or beginning of June, in which month it spawns. It never deferts the place s and is constantly taken except in hard frost. It is also found on other coasts of our island. The length is

above

Athetic.

The Atheroma above 42 inches, and the tail is much forked. first is semipellucid, covered with scales; the colour filvery, tinged with yellow; beneath the fide line is a row of small black spots. 2. The menidea, with 24 rays in the fin next the anus. This is a very small pellucid fish, with many black points interspersed; it has many teeth in the lips, but none in the tongue or jaws. It is found in the fresh waters of Carolina, and spawns in April.

ATHEROMA, in furgery, a tumour without pain or discoloration of the skin, containing, in a membranous bag, matter resembling pap, intermixed with hard and stony particles. These tumours are easily cured by incision.

ATHERTON, or ATHERSTON, a town of Warwickshire in England, situated on the river Stour, in W. Lon. 1. 30. N. Lat. 52. 40. It is a confiderable town, and had formerly a monuflery; but now is best known by its fair, which is the greatest in England for cheefe

ATHESIS (anc. geog.), a river of the Chalpine Gaul, which, riving in the Rhetian Alps, in Mount Brenna, in the county of Tirol, runs fouthwards and walkes Tridenton and Verona, which last it divides ; and after patting this, pends its courie eathwrite, in a parallel direction with the Fo; and falls into the fiddinate between Voting Claudie and Fillithings, a spranged the Eugenes, as another proper awding parallel eather are stated or fire and Finnish (Piny). Its modern matter the Eugenes.

the state of the same of the s formed from a defly without, there were the tent to be a second of the second ed their amagonist: hence they fed altogether on dry, folid, and viscous meats. In the earlier days, their chief food was dry figs and cheefe, which was called wilds formalle, have reson, and Armen designs woulder. Officialities or, as others fay, Pythagoras, first brought this is diffee, and substituted fiesh in lieu thereof. They had a peculiar bread called *** They exercised, est, and drank, without ceafing : they were not allowed to leave off eating when fatiated; but were obliged to crain on till they could hold no more; by which means they at length acquired a degree of voracity which to us feems incredible, and a strength proportional. Witness what Paulanias relates of the four celebrated athlete, Polydamus the Thessalian, Milo the Crotonian, Theagenes the Thasian, and Euthymus the Locrian:

The fecond is faid to have carried a bull on his back. Athlone a confiderable way, then to have knocked him down with a blow of his fift, and laftly, as some add, devoured him at a meal.

ATHLONE, a town of Westmeath in Ireland, lying in W. Long. S. o. N. Lat. 53. 20. It is fituated on both fides of the Shannon, and both parts are united by a strong, high raised, and well built bridge, in the middle of which stands a monument, with some figures cut in marble, together with Queen Elizabeth's arms, and fome inferiptions declaring the time and the founders of the building. The callle was founded by King John on some land belonging to St Peter's abbey, for which he granted a compensation. It is built on a high raifed round hill, refembling one of the Danish raths or forts. Here were formerly two convents or monafteries. Athlone was formerly firongly fortified, and considered as of very great importance. In the year 1601, a part of the English army under General Ginekle, in the very face of the Irish, who were trengly intrenched on the opposite shore, fording the river, formed, and took possession of the town, not loting more than 50 men in the attack; which is eftermed as bold and fuccefsful an enterprise as any recorded in history. There are generally two troops of horse and four companies of foot quartered at Athlone. This town gives the title of earl to the family of Ginckle, as a reward for the noble fervices performed by the general.

ATHOL, the most northern district of Perthshire in Scotland, extending in length 43 miles, and in breadth 30. It is bordered on the north by Badenoch, on the west by Lochaber, on the east and fouth-cast by Mar and Gowrie, on the fouth by Stratherne and Perth Proper, and on the fouth-west by Braidalbane. The soustry is very rough and mountainous, and conthins part of the ancient Caledonian forest; but these mountains are interspersed with fruitful valleys. Here are several villages, but no towns of any confideration. The most noted place is Blair Castle, scated on the river Tilt, near its influx into the Gurry, a pleafant limpid fiream that falls into the Tay. This cuttle belongs to the duke of Athol, who derives his title from this district, and lives here with great magnificence. Is the same neighbourhood we see the pass of Gillicraftley, rendered memorable by the battle fought here in the beginning of King William's reign, between that monarch's general M'Kay and the Highlanders adhering to King James. See GILLICRANKY.

ATHOS, a celebrated mountain of Chalcidia in Macedonia, fituated in E. Long. 26. 20. N. Lat. 40. 10. The ancients entertained extravagant notions concerning its height. Mela affirmed it to be so high as to reach above the clouds; and Martianus Capellinus, that it was fix miles high. It was a received opinion that the fummit of Mount Athos was above the middle region of the air, and that it it never rained three; because the ashes left on the altars erected near its summit were always found as they were left, dry and unfcattered. But if on many accounts it was famous among the ancients, it is no less so among the moderns. The Greeks, struck with its fingular situation and the venerable appearance of its towering afcent, erected fo many churches, monasteries, hermitages, &c. upon it, that it became in a manner inhabited by devotces, and from

Athos Athy.

thence received the name of the Holy Mountain; which name it still retains, though many of those consecrated works are now decayed. According to the accounts of modern travellers, this mountain advances into the Archipelago, being joined to the continent by an isthmus about half a league in breadth. It is about 30 miles in circumference, and two in perpendicular height. It may be travelled over in about three days, and may be feen 90 miles off. There is a fine prospect from the top; but, like all other high mountains, the cold on its fummit is excessive. It abounds with many different kinds of plants and trees, particularly the pine and fir. In the valleys grows a plant called elegia, whole branches ferve to make pens for writing. In thort, this mountain is faid to be adorned with variety of herbage and evergreens, a multitude of springs and streams, and woods growing near the shore, so as to be one of the most agreeable places in the world.

It is now inhabited by Caloyers, a fort of Greek, monks, of the order of St Bafil, who never marry, though others of that church do. They abitain from flesh, and fare very hardly, their ordinary meal being olives pickled when they are ripe. They are about-6000 in all, and inhabit several parts of the mountain. on which are 24 large old monasteries, surrounded with high walls for a defence against banditti. They are fo respected, that the Turks themselves will often fend them alms. These monks are not idle like others; but labour with the axe, spade, and fickle, dreffing themfelves like hermits. Formerly they had fine Greek manufcripts; but are now become so illiterate, that

they can fcarce read or write. Through this mountain, or rather through the ifthmus behind it, Xerxes king of Persia is said to have cut a passage for his flect when about to invade Greece, In this work he spent three whole years, and employ ed in it all the forces on board his fleet. He is also faid, before the work was begun, to have written the following infolent and ridiculous letter to the mountain: "Athos, thou proud and aspiring mountain, thou liftell up thy head to the very fkies, I advile thee not to be so audacious as to put rocks and stones that cannot be cut in the way of my workmen. If then makest that opposition, I will cut thee entirely down, and throw thee headlong into the fea." The directors of this enterprise are faid to have been Bubaris the for of Megabyzus, and Artacheus, the fon of Arbeus, both Perhans; but as no traces of fuch a great work remain, the truth of the whole relation has justly been called in quellion.

ATHWART, in navigation, is fynonymous with across the line of the course.

ATHE SET the Fore-foot, is a phrase that denotes the flight of a cannon ball from one thip across the course of another, to intercept the latter, and oblige her to fhorten fail, that the former may come near enough to examine her.

ATHWART-Hause, expresses the situation of a ship, when the is driven by wind or tide, or any other accident, across the fore-part of another.

ATHWART-Ships, reaching across ships from one side

ATHY, a town of Ireland in the county of Kildare, not far from the borders of Queen's county. W. Long. 7. o. N. Lat. 53. o. It is fituated on the Atibar river Barrow; is governed by a fovereign, two bailiffs, and a recorder; and is, alternately with Naas, the affizes town.

ATIBAR, the name by which the inhabitants of the kingdom of Gago in Africa call gold duft; from which word, Europeans, and especially the French, have composed the word tibir, which also fignifies gold dust among those who trade in that commodity.

ATIGNY, an ancient town of Champagne in France, where feveral of the kings of France had their refidence. It is feated on the river Aifne, in E. Long.

4. 47. N. Lat. 49. 30.

ATKINS (Sir Robert), lord chief baron of the exchequer, was born in 1621, and educated at the university of Oxford, from whence he removed to the inns. of court, and became eminent in the law. He was made knight of the Bath, with many other persons of the first distinction, at the coronation of King Charles 11. In 1672, he was appointed one of the judges of common pleas; in which honourable dation he continued till 1679, when, forefreing the troubles that foon after enfued, he thought fit to milita, and retire hato the country. In 1000, he was made by King the fame time executed the office of speaker to the house of lords, which had been previously refused by the marries of finishes. Ite dring instead himself by an unlinken acat for the laws and liberties of his country. He wrote toyend pages, which have been collected into one wollected from the first the tribe of Parlumentary and Political grade. The authors of the Biographia Britannica remove, that whoever inclines to be thoroughly information the resonant of the revolution, tion, ese di GULL Incle aged 88

ATTEN born in 1645, could adorn

famile, and was post a subsequent of contraction in the year stage. It was a scattle a contraction whereon he removed to Lincoln may are subsequent of thought on the subsequent of the contraction has been subsequent for whom he smalled a troop of horiz at his subsequent pence. At the Reftoration he was made and of the deputy lieutenauts of Gloucestershire, and distinguish ed himself by his attachment to the government. But at length being committed prisoner to the Market fea in Southwark for debt, he died there on the said of September 1677. He wrote several press, pastcularly A Treatife on the Original and Growth of Printing

ATLANTIC OCEAN, that bounded by Europe and Africa on the east, and by America on the west,

ATLANTICA. See ATLANTIS.

ATLANTIDES, in astronomy, a denomination given to the Pleiades, or feven flars, fometimes alfocalled Vergillia. They are thus called as being suppoAtlantis. Sed by the poets to have been the daughters either of Atlas or his brother Hesperus, who were translated in-

> ATLANTIS, ATALANTIS, OF ATLANTICA, an island mentioned by Plato and some others of the ancients, concerning the real existence of which many disputes have been raised. Homer, Horace, and the other poets make two Atlanticas, calling them Hefperides and Elysian Fields, making them the habita-tions of the blessed. The most distinct account of this island we have in Plato's Timæus, of which Mr Chambers gives the following abridgement: " The Atlantis was a large island in the western ocean, situated before or apposite to the straits of Gades. Out of this island there was an easy passage into some others, which lay near a large continent exceeding in bigness all Europe and Asia. Neptune settled in this island (from whose fon Atlas its name was derived), and divided it among his ten fons. To the youngest fell the extremity of the island, called Gadir, which in the language of the country signifies fertile, or abundant in sheep. The defeendants of Neptune reigned here from father to fon for a great number of generations in the order of primogeniture, during the space of 9000 years. They alfo possessed several other islands; and, patting into Europe and Africa, fundated all Libys as far as Egypt, and all Europe to Afia Miner. At length the island link under water, and for a long time afterwards the feas thereabouts was full of rucks and shelves."

existence of the Atlanta is not to be looked upon as entirely fabulous. Some take it to have been Ameriseely feellowed up by the norm as Plato afferts; and that these small islands are the thattered remains of it which were left flanding.

Arnauris (New), is the name of a fictitious philosophical commonwealth, of which a description has been given by Lord Bacon. The New Atlantis is fuppoied to be an island in the South feet to which the author was driven in a voyage from Peru to han. The composition is an ingenious fable, formed after, the manner of the Utopia of Sir Thomas More, or Campanella's City of the Sun. Its chief delign is to. exhibit a model or description of a college, inflituted for the interpretation of nature and the production of great and marvellous works, for the benefit of men, under the name of Solomon's Houft, or "the college of the fix days work." Thus much, at least, is finished; and with great beauty and magnificence. The author proposed also a frame of laws, or of the best state or mould of a commonwealth. But this part is not executcd.

ATLAS, king of Mauritania, a great astronomer. Atlas. contemporary with Moses. From his taking observations of the stars from a mountain, the poets feigned him to have been turned into a mountain, and to fustain the heavens on his shoulders. Being an excellent astronomer, and the first who taught the doctrine of the fphere, they tell us that his daughters were turned into stars; seven of them forming the Pleiades, and other seven the Hyades.

ATLAS, a chain of mountains in Africa, lying between the 20th and 25th degree of north latitude, and supposed almost to divide the continent from east. to west. They are said to have derived their name from Atlas king of Mauritania, who was a great aftronomer. They were greatly celebrated by the ancients on account of their height, infomuch that the above-mentioned king, who is faid to have been trantformed into a mountain, was feigned to bear up the heavens on his shoulders. We are assured, however, by Dr Shaw, that the part of this chain of mountains which fell under his observation could not fland in competition either with the Alps or Apennines. He tells us, that if we conceive a number of hills, ufually of the perpendicular height of 400, 500, or 600 yards, with an easy ascent, and several groves of fruit or forest trees, rising up in a succession of ranges above one another; and that if to this prospect we add now and then a rocky precipice, and on the fuminit of each imagine a miserable mud-walled village; we shall then have a just idea of the mountains of Atlas.

According to M. Chemer +, this mountain is form- + Iliff of ed by an endless chain of lofty eminences, divided into Marine, different countries, inhabited by a multitude of tribes, 1. 1.2. whole ferocity permits no stranger to approach. " I have not been able (continues he) to obtain a fufficient knowledge of these mountains to describe them accurately: What Leo Africanus has faid of them is very vague; and his account is the lefs to be regarded at present, as it is now about three centuries fince he wrote, and the face of the country has been in that time totally changed. Nothing perhaps would be more interesting to the curiofity of the philosopher, or conduce more to the improvement of our knowledge in natural history, than a journey over Mount Atlas. The climate, though extremely cold in winter, is very healthy and pleasant; the valleys are well cultivated, abound in fruits, and are diverlified by forests and plentiful fprings, the streams of which uniting at a little distance form great rivers, and lose themselves in the ocean. According to the reports of the Moors, there are many quarries of marble, granite, and other valuable stone, in these mountains: It is probable there are also mines, but the inhabitants have no idea of these riches; they consider their liberty, which their situation enables them to defend, as the most inestimable of all treafures."

ATLAS, in matters of literature, denotes a book of univerfal geography, containing maps of all the known parts of the world.

ATLAS, in commerce, a filk fatin, manufactured in the East Indies. There are some plain, some striped, and some flowered, the flowers of which are either gold or only filk. There are atlasses of all colours, but most of them false, especially the red and the crimton. The manufacture of them is admirable; the golds

Atmo-Aphere.

fluids.

and filk being worked together after fuch a manner as no workman in Europe can imitate; yet they are very far from having that fine gloss and lustre which the French know how to give to their filk stuffs. In the Chincle manufactures of this fort, they gild paper on one fide with leaf gold; then cut it in long flips, and weave it into their filks; which makes them, with very little coft, look very rich and fine. The same long flips are twifted or turned about filk threads, fo artificially, as to look finer than gold thread, though it be of no greater value.

ATMOSPHERE, a word generally used to signify Atmosphere com-the whole mass of fluid consisting of air, aqueous and Posed of two other vapours, electric fluid, &c. surrounding the earth different

to a confiderable height.

The composition of that part of our atmosphere properly called air, was till lately very much unknown. In former times it was supposed to be a simple, homegeneous, and elementary fluid. The experiments of Dr Priestley discovered, that the purest kind of air, which he called dephlogiflicated, was in reality a compound, and might be artificially produced in various ways. His first conjectures concerning its component parts were, that it confilted of earth, nitrous seid, soid phlogiston. Subsequent experiments rendered these conjectures dubious; and at last it was supposed that dephlogisticated air is a pure elementary substance, the vivifying principle to animals, and the acidifying principle throughout all nature. This dephlogificated air, however, is but a small part of the composition of our atmosphere. According to the most securate computations, the air we usually breathe is composed of only one-fourth of this dephlogifticated air, or perhaps lefs; the other three or four parts confifting of what Dr Prieftlev calls phlogificated, and M. Lavoiher mephitic air. This by itself is absolutely noxious, and exceedingly poisonous to animals: though it feesis only to be negatively fo; for when mixed in a certain proportion with dephlogisticated air, it may be breathand dephiloed with fafety, which could not be if it contained any ingredient absolutely unfriendly to the human confidence vegetables, tution. The other part, viz. the pure dephlogifficmed air, feems to fland much in the fame relation to plants that phlogisticated air does to animals; that is, it would prove poisonous and destroy them if they were to depend upon it entirely for their subfiftence; but as they derive their nourishment partly from the air and partly from the foil, it thence happens, that the plants which are fet to grow in dephlogifticated air do not die influntly, as animals do in the phlogisticated kind, but remain for some time weak and fickly.

The other component parts of our atmosphere are for quantity of various, and of such heterogeneous natures, that they do not admit of any kind of definition or analysis, one only excepted, namely, the elettric fluid. This we know pervades the whole, but appears to be much more copious in the upper than in the lower atmospherical regions. See ELECTRICITY. To measure the absolute quantity of this fluid, either in the atmosphere or any other substance, is impossible. All that we can know on this subject is, that the electric shud pervades the atmosphere; that it appears to be more abundant in the superior than the inferior regions; that it feems to be the immediate bond of connexion between the atmosphere and the water which is suspended in it; and that by its various operations, the phenomena of hail, rain, fnow, lightning, and various other kinds of iphere. meteors, are occasioned. See RAIN, HAIL, SNOW,

Various attempts have been made to afcertain the Calculaheight to which the atmosphere is extended all round tions of the the earth. These commenced soon after it was disco-height of vered, by means of the Torricclian tube, that air is a the atmogravitating fuhrance. Thus it also became known, that a column of air, whose base is a square inch, and the height that of the whole atmosphere, weighs 15 pounds: and that the weight of air is to that of mercury, as 1 to 10,800: whence it follows, that if the weight of the atmosphere be sufficient to raise a column of mercury to the height of 30 inches, the height of the aerial column must be 10,800 times as much. and confequently a little more than five miles high.

It was not, however, at any time supposed, that this calculation could be just; for as the air is an elastic fluid, the upper parts mult expand to an immense bulk, and thus resider the calculation above related exceedingly errestedus. By experiments made in different countries, it has been found, that the spaces which any portion of sicrakes up, are reciprocally proportional to the weights with which it is compared. Allowances were therefore to be stand in proportion the height of the atmosphere. It was propose the height of the whole disided into immunication of and parts, the density of each of which is no its positive; and the weight of the whole incumbent amorphises being also as its quantity of its evident, that the weight of the incumbent air weight of the incumbent air weight of the incumbent air is everywhere as the quantity contained in the fubis everywhere as the quartity contained in the fubjacent part; which makes a difference between the
weights of each two that the differences of magnitudes the

continue.

It a reason to the continue of the the sir algest to have had, it was suspected that the upper parts of the atmospherical regions were not folject to the same laws with the lower ones. Thilleto Height of phers therefore had recourse to another method for de it determitermining the altitude of the atmosphere, viza by a call ned from culation of the height from which the light of the the beginis refracted, fo as to become visible to us before the ming and himself is feen in the heavens. By this method it was light. determined, that at the height of 45 miles the atmofphere had no power of refraction; and confequently beyond that distance was either a mere vacuum or the

next thing to it, and not to be regarded. This theory foon became very generally received. and the height of the atmosphere was spoken of as fa-

Atmoiphere. 6 Objection

miliarly as the height of a mountain, and reckoned to be as well afcertained, if not more fo, than the heights of molt mountains are. Very great objections, however, which have never yet been removed, acide from the appearances of fome meters, like large globes of app arane, fire, not infrequently to be field at vaft heights above et meteors, the crith (See Merror). A very remarkable one of this kind was objected by the Halley in the month of Mach 1719, whole altitude he computed to have been between 60 and 733 Paghih miles; its diameter 2800 yirds, or upwirds of a unle and a half; and its velocity about 300 index in a minute. Others, apparently of the fame kind, but whose altitude and velocity were fill greater, have been observed; particularly that very remarkable one, August 18, 1783, whose distance from the earth could not be less than 90 miles, and its diameter not less than the former; at the same time that its velocity was certainly not less than 1000 miles in a minute. Fire balls, in appearance fimilar to thefe, though vaftly inferior in fize, have been sometunes observed at the surface of the carrie. Of this kind Dr Priettley mentions and feet in board the Montague, 4th November 1740, which impressed as big as a large millitone, and broke with a molent explosion.

plotion.

From analogical registrates, a letter very probable, that the success which plots in the first ball just mathematically are not with on the furface of the earth. The probleming circumstances with report to the former are than at the great leights above mentioned, the simulations are commonly furceeded by one or many applications are commonly furceeded by one or many applications after the former are foretimes faid to be accompanied with a saling motic as they pade over our heads.

The pade over our heads the saling motic as they pade over our heads.

The saling with the saling and feeling to saling the saling and feeling to saling the saling saling and feeling to saling the saling saling and feeling to saling the saling saling and feeling to saling a saling motic was saling as saling. Dr. Halley acknowledged that he are applied as reconsider the saling motic was saling as saling. Dr. Halley acknowledged that he is a saling as reconsider the leight of the atmosphere; as, in the regions in which height of the atmosphere; as, in the regions in which this meteor moved, the air ought to have been 500,000 times more rare than what we breathe, and the next thing to a perfect vacuum.

In the meteor of 1783, the difficulty is hill prester, as it appears to have been so miles farther up in the air. Dr Halley offers a conjecture, indeed, that the vast magnitude of such bodies might compensate for the thirmess of the medium in which they moved. Whether or not this was the case cannot indeed be espertained, as we have so few data to go upon; but the greatest dissiculty is to account for the brightness of the light. Appearances of this kind are indeed with great probability attributed to electricity, but the difficulty is not thus removed. Though the electrical fine pervades with great eafe the vacuum of a common hir pump, yet it does not in that case appear in bright vell defined sparks, as in the open air, but rather in

long streams resembling the aurora borealis. From fome late experiments, indeed, Mr Morgan concludes, iphere. that the electrical fluid cannot penetrate a perfect vacuum *. If this is the case, it shows that the regions * See Elso we speak of are not such a perfect vacuum as can be tricity. In artificially made; but whether it is or not, the ex-dex. treme brightness of the light shows that a sluid was present in those regions, capable of confining and condenling the electric matter as much as the air does at the furface of the ground; for the brightness of these meteors, confidering their distance, cannot be suppofeel inferior to that of the brightest flashes of light-

This being the case, it appears reasonable to conclude, Density of that what is called the deafity of the air does not alto- the air does gether keep pace with its gravity. The latter indeed not always must in a great measure be affected by the vapours, with its but above all by the quantity of the batis of fixed or gravity, dephlogiflicated air contained in it: for Mr Knwan has discovered that the basis of fixed air, when deprived of its elaftic principle, is not greatly inferior to gold in specific gravity; and we cannot suppose that of dephlogisticated air to be much less. It is possible, therefore, that pure air, could it be deprived of all the water it contains, might have very little gravity; and as there is great reason to believe that the basis of dephlogisticated air is only one of the constituent parts of water +, we fee an evident reason why the air + See De of water \(\dagger, we see an evident reason why the an analog large fit for respectively. The ought to become lighter, and likewise less fit for respectively. The desired is and ration, the higher up we go, though there is a possible Water. lity that its dentity, or power of supporting flame, may continue unaltered.

There are not yet, however, a fufficient number of facts to enable us to determine this question; though fuch as have been discovered seem rather to savour the above conjecture. Dr Poerhaave was of opinion that the gravity of the air depended entirely on the water it contained; and, by the means of alkaline falts, he was enabled to extract as much water from a quantity of air as was very nearly equivalent to its weight. By the calcination of metals we may extract as much of the hatis of dephlogisticated air from a quantity of atmo-Spherical air as is equivalent to the weight of air lott. Were it pollible, therefore, to extract the whole of this, as well as all other vapours, and to preferve only the elastic principle, it is highly probable that its gravity would entirely ceale. It has been found by those who have accended with aeroftatic machines, or to the tops of high mountains, that the dephlogificated air is found to be contained in fmaller quantities in the atmaishere of these elevated regions than on the lower grounds. It is also found, that in such situations the air a spech drier, and parts with water with much more difficulty, than on the ordinary furface. Salt of tartar, for inftence, which at the foot of a mountain will very foon run into a liquid, remains for a long time exposed to the air on the top of it, without showing the least tendency to deliquesce. Nevertheless, it hath never been observed that fires did not burn as intensely on the tops of the highest mountains as on the plain. The matter indeed was put to the trial in the great eruption of Vesuvius in 1779, where, though the lava spouted up to the height of three miles above the

level of the fea, the uppermost parts all the while were

to appearance as much inflamed as the lowest.

The

Atmosphere.

Gravity of the upper regions of the atmohaps diminated by

The high degree of electricity, always existing in the upper regions of the atmosphere, must of necessity have a very confiderable influence on the gravity of any heterogeneous particles floating in it. When we confider the effects of the electric fluid upon light bodies at the furface of the earth, it will readily be admitted. that in those regions where this fluid is very abundant, the gravity of the atmosphere may be much diminished without affecting its dentity. We know that it is the electricity, nature of any electrified fubiliance to attract light bodies; and that, by proper management, they may even be fuspended in the air, without either moving up or Jown for a confiderable time. If this is the cafe with hight terrestrial bodies, it cannot be thought very improbable that the aerial particles themselves, i. e. those which we call the basis of dephlogisticated air, and of aqueous or other vapour diffuled among them, should be thus affected in the regions where electricity is for abundant. From this cause, therefore, also the gravity of the atmosphere may be affected without any alteration at all being made in its denfity; and hence may arile anomalies in the barometer hitherto not taken notice of.

Abfolute height of tphere un-

It appears, therefore, that the absolute height of the atmosphere is not yet determined. The beginning and ending of twilight indeed show, that the height determined at which the atmosphere begins to refract the fun's light is about 44 or 45 English miles. But this may not improbably be only the height to which the aqueous vapours are carried: for it cannot be thought any inregionable supposition, that light is refracted only by means of the aqueous vapour contained in the atmosphere; and that where this ceases, it is still capable of supporting the elettric fire at least, as bright and strong as at the surface. That it does extend much higher, is evident from the meteors already mentioned: for all thefe are undoubtedly carried along with the atmosphere; otherwise that of 1783, which was seen for about a minute, must have been left 1000 miles to the westward, by the earth flying out below it in its annual courfe round the fun.

Of the pref-

It has already been mentioned, that the pressure of forc of the the atmosphere, when in its mean state, is equivalent atmosphere, to a weight of 15 pounds on every square inch. Hence 1)r Cotes computed, that the preflure of the whole amiscut fluid upon the earth's furface is equivalent to that of a globe of lead 60 miles in diameter. Hence also it appears, that the pressure upon a human body must he very confiderable; for as every square inch of surface fullains a pressure of 15 pounds, every square foot, as containing 144 inches, must fustain a pressure of 2160; and if we suppose a man's body to contain 15 iquare feet of furface, which is pretty near the truth, he must sustain a weight of 32,400 pounds, or 16 tun, for his ordinary load. By this enormous pressure we should undoubtedly be crushed in a moment, were not all parts of our bodies filled either with air or some other classic fluid, the spring of which is just sufficient to counterbalance the weight of the atmosphere. But whatever this fluid may be, we are fure that it is just able to counteract the atmospherical gravity and no more; for if any confiderable pressure be superadded to that of the air, as by going into deep water, or the like, it is always feverely felt, let it be ever fo equable. If the pressure of the atmosphere is taken off

from any part of the Lonan body, the hand, for inflance, when put in an open reserver from whence the air is afterwards extracted, the weight of the atmofohere then discovers med, and we magaze the hand firongly fucked down into the glafe. See Phruma-

Inhere.

In countries at fome diffuser from the equitor, the Variation preffure of the atmosphere varies to deterably, and thus of the prefproduces confiderable changes on many terrellial bofure, and dies. On the human body the quantity of proffure fometimes varies near a whole ton; and when it is thus fo much diminished, most people find fomething of a liftleffness and inactivity about them. It is furprifing. however, that the spring of the internal fluid, already mentioned, which acts as a counterposte to the atmofpherical gravity, should in all cases feem to keep pace with it when the preffure is naturally diminished, and even when it is artificially augmented, though not when the pressure is artificially diminished. Thus in that kind of weather when the pressure of the air is leaft, we never perceive our veins to swell, or are fenfible of any inward espansion in our bodies. On the contrary, the throughtion is languid, and we feem rather to be suprelled by a weight. Even in going up Of difficulto the tops of monutains, where the pressure of the at-ty of respimosphere is distinished more than three times what it ration on the tops of usually is on the plant, and luch appearances are ob-mountains ferred. Some transfers indeed have affirmed, that, on the tops of very bigh minimizing, the sir is is light as to occasion a great difficulty of respiration, and even to occasion a great Afficiently of respiration, and even violent retching and comiting of blood. It does not appear, however, that these affections are well founded. Mr Brydisch found no deconvenience of this kind on the top of Manual Strate and use much thing mentioned by Mr. That I, who also afcended this mountain. Sir Whiten Handle and accorded this mountain. Sir Whiten Handle and affected any that he did feel a different series and the stop of a volcato, the respiration was a series of the many different causes, that it is personnel and the same that the personnel strate one. The French mathematiciant, when on the top of a next high peak of the Anges, did not make any claim that of this kind, though they lived them for four tonic sing. On the contrary, they found the wind to extremely On the contrary, they lound the wind to extremely violent, that they were fearer able to withstand its force; which feems an argument for at least equal denfity of the atmosphere in the superior as in the inferior regions. Dr Heberden, who ascended to the top of Teneriffe, a higher mountain than Atna, makes no mention of any difficulty of respiration. M. Saussure, M. Saus however, in his journey to the top of Mount Blanc, the fare's fymy highest of the Alps, felt very great uneafiness in this toms on the way. His respiration was not only extremely difficulty of cult, but his pulse became quick, and he was seized Blanc with all the symptoms of a sever. His strength, was counte for also exhausted to such a degree, that he seemed to require four times as long a space to perform some experiments on the top of the mountain as he would have done at the foot of it. It must be observed, however, that these symptoms did not begin to appear till he had afcended two miles and a half perpendicular above the level of the fea. The mountain is only about a quarter of a mile higher; and in this short space he was reduced to the fituation just mentioned. But it

is improbable that so small a difference, even at the end

A.mo. of his journey, should have produced such violent eflphere... feets, had not fome other cause concurred. A cause of this kind he himfelf mentions, viz. that the atmofplace at the top of the mountain was in much impregnated with fixed air, that bine witer, exposed to it, quickly became covered with a pelliph occasioned by the autorption of that fluid. Now it is known. that fixed air is extremely per ucious to animals, and world bring on fymptom; findar to thole above-mentioned. There is no reason, therefore, to have recourse to the rarity of the atmosphere for folving a phenomenon which may more naturally be accounted for otherwise.

> When the preffure of the atmosphere is augmented, by defeending, in the diving-bell, to confiderable depths in the fea, it does not appear that any inconvenience follows from its increase. Those who its in the divingbell are not sensible of any proflute as long as they remain in the air, though they feel it very fentibly in go. ing into the water's yet it is certain, that the prefime in both cafes is the fames for the whole preffere of the atmosphere, as well as of the water, is all select by the air in the diving bell, and conferenced to those who fit in it.

air in the diving-bell, and conference of the ministed to those who die in it.

But though artificial contine floor of the air, as well as natural artificial contine floor of the air, as well as natural artificial contine floor of the air, as well as natural artificial contine floor of the air, as well as natural artificial contine floor of the air, and that below it a conducted by its own the parts of which are separable, and which is a real and the form any time in an attribution of the minister on the coulders from any time in an attribution of the air, and that the parts of which are separable, and which is a real and the parts of which are separable, and which is a real and the parts of which are separable to the dentity of fire and loght, though the forms inclined to believe it. M. de Luc compared to the dentity of fire and loght, though the forms inclined to believe it. M. de Luc compared the two times of gravity in the art is, however, the three contents of the air, and the contined to believe it. M. de Luc compared the part is a separable by inclined the part is a separable to the contined to believe it. M. de Luc compared the separable by inclined the part is a separable to the contined to believe it. M. de Luc compared the forms of gravity in the art is, however, the separable by inclined the part is a separable by inclined the part is a separable by inclined the part is an attribution of the gravity of the airs, and the substitute of the airs and the substitute of the airs, and the substitute of the airs and mixing with it or feeting hoole a non-gravitating builds which did not act in such large proportion in any pate ticular place before. No doubt, the action of the latent heat and electric fluid is the same in the torrid as in the temperate zones: but in the torrid zone the tolar heat and excessive evaporation counteract them; so that whatever quantities may be discharged by the excessive deluges of rain, &c. which fall in those countries, they are instantly absorbed by the abundant sluid, and are quickly ready to be discharged again; while, in the temperate zones, the air becomes fensibly lighter, Vol. II. Part II.

as well as warmer, by them for lone time before they can be abforbed again.

The variations of heat and cold to which the aninfahere is fulfect, have been the fulficit of much species Verticion fation. To general they form to depend energy upon a creation the light of the fun reflected into the atmosphere from reduced of the earth; and where this reflection is deficient, even the secothrough the light should be present ever to much, the labore most violent degrees of cold are found to take place. Hence, on the tops of mountains, the cold is generally excellive, though by reason of the clearness of the atmosphere the light of the fun falls upon them an orenter quantity than it can do on an equal space on the plain. In long winding passages also, such as the caverus of Alton and Veluvius, where the air has room to circulate freely, without any access of the fun, the cold is fearce tolerable; whence the use of these for cooling liquors, preferving meat, &c.

The coldness of the atmosphere on the tops of mountain the tains has been afcribed, by M. Lambert and De Luie, "AD to the igneous fluid, or elementary fire, being more rare but to remain those clevated fituations than on the plant. M. Lambert is of only in the best is of only in that it is considered above by the state of the the bert is of opinion that it is rarefied above by the action n_1 of the air, and that below it is condensed by its own a write we

M. Sausure, in treating of this subject in his ac- vi defe count of the Alps, does not confider five as a find fo far free said detached as to be able either to afcend with ra- "" wore it does not appear that in this diffribution the fituation of places, with regard to the horizon, has any sther influence than what they receive from the duferent currents produced by the dilatation of the air, and by the levity which that dilatation produces. The afcent of flame, Imoke, &c. or of air heated in any way, perfuaded the ancients that fire is possessed of abfolute levity, by which it had a tendency to mount upwards. "But thefe effects (tays he) are owing either to the levity of the fluid which conflitutes flame, or to that of air dilated by heat; and not to the levity of the

igueous fluid. I am, however, fufficiently convinced, that this fluid is incomparably lighter than air, though I do not believe that it possesses the power of ascending in our atmosphere by virtue of its levity alone.

32 M. Bouguer's rea-

"The celebrated Bouguer has demonstrated, by for for the principles the most simple, and most universally adoptcold on the cd, that it is not necessary, in order to account for the top of the diminution of heat on mountains, to have recourse to hypothesis that are at best doubtful. The following is his explanation of what was felt on the mountains of Peru:

" It was proper, in order to explain this fubject, to infift on the short duration of the sun's rays, which cannot firike the different fides of mountains but for a few hours, and even this is not always. A horizontal plain, when the fun is clear, is experted at mid-day to the perpendicular and undiminished action of these rays, while they fall but obliquely on a plain not much inclined, or on the fides of a high pile of fleep rocks. But let us conceive for a moment an infulated point, half the height of the atmosphere, at a distance from all mountains, as well as from the clouds which float in the air. The more a medium is transparent, the lefs heat it ought to receive by the immediate action of the fun. The free passage which a very transparent body allows to the rays of light, shows that its fmall particles are hardly touched by them. Indeed what impression could they make on it, when they pass thro' almost without obstruction? Light, when it consists of parallel rays, does not by passing through a foot of free atmospheric air, near the earth, lose a hondred thousandth part of its force. From this we may judge how few rays are weakened, or can act on this said, in their passage through a firatum of the diameter not of an inch or a line, but of a particle. Yet the subtility and transparency are fill greater at great heights, as was obvious on the Cordilleras, when we looked we dis frant objects. Laftly, The groffer air is heated below by the contact or neighbourhood of bodies of greater dentity than itself, which it furrounds, and on which it refts; and the heat may be communicated by thate and little to a certain distance. The inferior parts of the atmosphere by this means contract daily a very coniderable degree of heat, and may receive it is proposrion to its denfity or bulk. But it is evident than the tame thing cannot happen at the distance of a league and a half or two leagues above the farface of the earth, although the light there may be fomething more active. The air and the wind therefore must at this height be extremely cold, and colder in prepartion to the elevation.

" Befides, the heat necessary to like it not merely that which we receive every infrant from the fun. The momentary degree of this heat corresponds to a very imall part of that which all the bodies around ut have imbibed, and by which ours is chiefly regulated. The action of the fun only ferves to maintain nearly in the fame thate the fum of the total heat, by repairing thro the day the lofs it full nine through the night, and at times. If the addition be greater than the lofs, the Mal heat will increase, as it happens in summer, and will continue to accumulate in a certain degree; but to the reasons already given, this accumulation canlikes very great on the top of a mountain, where the ble. t, which rifes high, is never of great bulk. The lowest state of the thermometer in every place is always in proportion to the heat acquired by the foil; and that heat being very small on the top of a mountain, the quantity added to it by the fun during the day must be comparatively greater; and the accumulated heat will be more in a condition to receive increase in proportion to its distance from the degree which it cannot pafs.

44 Another particular observable on all the high places of the Cordilleras, and which depends on the same cause, is, that when we leave the shade, and expole ourfelves to the funshine, we feel a much greater difference than we do here in our fine days when the weather is temperate. Every thing contributes at Outto to make the fun exceedingly powerful: a fingle Rep from an exposed place to the shade gives the fenfation of cold; this would not be the cafe if the quantiry of heat sensined by the foil were more confiderable. We now also see why the fame thermometer, put first into the fluide and then in the fun, does not undergo the same changes at all times and in all places. In the defining upon Pichincia, this infrument is generally a few legaces below the freezing point, which may be reckoned the natural temperature of the place; but when during the day we expedicit to the fun, it is easy techniques the effect and be great, and match more than distill it where you have been more fored."

This theory a ministra by C. Sauffere, to be and a rays, confidence of the first and independent of the first are entrince for the first and independent of new certains for the first are great on mountains at on plains; vin the first are at the first are considered to the first are considered to the first are considered to the first are considered. To the first are considered, with a second to the first are considered, with the first are considered, with the first are considered, with the first are considered. ried, with the same of the sam greater Sales chen, there is a second to the direct folar mysten the top of a high mountain had abo fame power as on the plan, while the body on with they acted was placed in fuelt a manuer as to be us section by the fattounding the War this purpole he inflitutions fer of experimental from which he drew the following conclusions, vir that a difference of 777 toiles in beight, diminifice the hour which the rays of the lan are able to communicate to a body exposed to the external sir, 14° of the thermometer; that it diminishes the heat of a body partially exposed, only 6°; and that it augments by so the heat of a third body completely defended from the mir.

Hence it appears that the atmosphere, though so Atmoeffentially necessary to the support of fire, is somehow sphere eveor other the greatest antagonist of heat, and most ef-rywhere sectually counteracts the operation of the folar rays in counteract producing it. This power it feems to exert at all di-the fun. stances, at the furface as well as in the higher regions. From some experiments made by M. Pietet, it appears,

Atmofphere.

21 a colder VECK PCAF he furface of the ground chan at ome ditance.

xperl-

ments on

his fub-

cA.

that even in places exposed to the rays of the fun, the heat, at five feet distance from the ground, is greater only by one or two degrees than at 50 feet above the furface, though the ground was at that time 15 or 200 warmer than the air immediately in contact with it. Inconfiderable as this difference is, however, it does not hold as we go higher up: for if it did, the cold on the top of the mountain of Saleve, which is 3000 feet above the level of the lake of Geneva, would be 60° greater than at the foot of it: whereas in reality it is only 10°. In the night-time the case is reversed; for the stratum of air, at five feet from the ground, was found by Mr Pietet to be colder than that at co. Besides this diffegent flasts of the atmosphere are found to pelicit very different and variable degrees of cold, without any regard to their fituation high up or low deten. In the year 1780, Dr Willon of Glasgow looks, a very samarkablecold existing close to the highest the ground? to that the thermometer, when laid on the further of the frow, funk many segroes lower than the disk ed 24 feet above it. It has been likewise these that in clear weather, though the finding of the be then most higher to be highest by the first water. the grains and a second of the grains and a second of the information that money are a second of the land to no show the true will that might take place in (a to)
shady northerly already and
open air. One open air. One state of the stat minima de chanda moving in a combin new legithic correct of air below. 43 direction to a ver cloudy nights the lowest thermometer sometimes thaned the heat to be a degree or two greater than the upper one; but in the day-time the heat below confrantly exceeded that above more than in the month of Oc-

To determine whether the nocturnal refrigeration was angmented by a nearer approach to the earth, two thermometers were placed in the midst of an open meadow, on the bank of the river near Canterbury, One was placed on the ground, and the other only fix At nofeet above it. The thermometer, at fix feet distance from the ground, agreed nearly with the former at nine feet; but the nocturnal variations were found to correspond entirely with the clearness or the cloudiness of the sky: and though they did not always happen in proportion to their respective altitudes, yet when the thermometers differed in any respect, that on the ground always indicated the greatest degree of cold.

The difference betwist these two thermometers, at the fmall distance of fix feet from each other, being found no less than three degrees and a half, the number of thermometers in the meadow was augmented to four. One was funk in the ground, another placed just upon it, and the third fuspended at three feet above it. Three others were placed on a rifing ground where the land was level with the cathedral tower, and about a mile diffant from it. One of these was likewife lunk in the ground, another placed just upon it, and a third fusionded fix feet above it. With their sever thermometers, and the two first mentioned. which were placed in the city, he continued his obferwations for 20 days; but as the weather happened to be cloudy during the whole of that space, excepting for leven or eight days, no confiderable variation hapmened excepting on their days. The refult of the experiments was, that the cold was generally greater in the valley than on the hill; but the variations between the thermometers on the ground and those fix feet

them, were often as great on the hill as in the the sook where at the distance of only three feet from the grants to the length of the thermometers hithe to made use of rendered it impossible to make any finaller distance. Two new ones, were formed by bending down the large or holb of the thermometer, to an holicit, while the stem remained in a vertical method the temperature might be obtained of a single inch. Sometimes, in the horizontal thermometers were the open ale one within an inch of the assisted, and the other nine inches above it. When the chisties among the other thermometers was confidera difference was likewife perceived between thefe; the lawer one fornetimes indicating more than two dethe heat then the upper one, though placed fo

Francisco California ents Mr. Sex concludes, that a His conclumater diffination of heat frequently takes place near flows from the day of the cape-tion day in the light class than at any altitude in the thric expe-tion places within the limits of his inquiry, that is, riments. set seet from the ground; and at fuch times the self degrees of cold are always met with nearest the select of the cuith.

This is a sauthant and regular operation of nature, under certain circumitances and dispositions of the atmolphers, and takes place at all feafons of the year; and this difference never happens in any confiderable degree but when the air is still, and the sky perfectly unclouded. The moiltest vapour, as dews and fogs, did not at all impede, but rather promote, the refrigeration. In very severe froits, when the air frequently deposites a quantity of frozen vapour, it is commonly

4 I 2 found found greatest; but the excess of heat which in the day time was found at the lowest station in summer, diminished in winter almost to nothing.

Mr Darthe rarefaction of air.

It has been observed, that a thermometer, included win's expe- in a receiver, always finks when the air begins to be riments on rarefied. This has been thought to arife, not from any degree of cold thus produced, but from the fudden expansion of the bulb of the thermometer in confequence of the removal of the atmospherical pressure: But from some late experiments related, Phil. Trans. Vol. LXXVIII. by Mr Darwin, it appears that the atmosphere always becomes warm by compression, and cold by dilatation from a compressed state. These experiments were,

1. The blaft from an air gue was repeatedly thrown upon the bulb of a thermometer, and it uniformly funk it about two degrees. In making this experiment, the thermometer was firmly fixed against a wall, and the air gun, after being charged, was left for an hour in its vicinity, that it might previously lofe the heat it had acquired in the act of charging; the mir was then discharged in a continued stream on the bulb of the thermometer, with the effect already mention-

2. A thermometer was fixed in a wooden tube, and fo applied to the receiver of an air gun, that, on difcharging the air by means of a ferew preffing on the valve of the receiver, a continued fiream of air, at the very time of its expantion, passed over the built of the thermometer. This experiment was four times repeated, and the thermometer uniformly funk from five to feven degrees. During the time of condensation there. was a great difference in the heat, as percoived by the hand, at the two ends of the condening fyriage: that next the air globe was almost painful to the touch; and the globe itself became hotter than could have been expected from its contact with the fyringe, it !! to this (fays Mr Darwin), that in exploding our war gun the stream of air always becomes visible, which is owing to the cold then produced precipitating the pour it contained; and if this ftream of air had been ? previously more condensed, or in greater quantity to as not initantly to acquire heat from the common atmosphere in its vicinity, it would probably have fallen in how.
